These are the rate and volume of water provided by the Supply Water Storage Tank.

Evaporative Fluid Cooler Water Starved By Storage Tank Rate [m3/s]

Evaporative Fluid Cooler Water Starved By Storage Tank [m3]

These are the rate and volume of water the Supply Water Storage Tank was not able to provide. The starved water is assumed to come from the mains. The fluid cooler's operation is not affected by a lack of storage tank water.

EvaporativeFluidCooler:TwoSpeed

The two-speed evaporative fluid cooler is modeled in a similar fashion to the single-speed evaporative fluid cooler. The evaporative fluid cooler is modeled as a counter flow heat exchanger with two-speed fan (induced draft configuration. See schematic diagram in EvaporativeFluidCooler:SingleSpeed section). The user must define fluid cooler performance via one of the three methods: design heat transfer coefficient-area product (UA) and design water flow rate, or standard fluid cooler design capacity at a specific rating point or design capacity at non standard conditions. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified.

The evaporative fluid cooler seeks to maintain the temperature of the water exiting the evaporative fluid cooler at (or below) a set point. The set point schedule value is defined by the field "Condenser Loop Temperature Setpoint Node Name or Reference" for the CondenserLoop object. The model first checks to see whether inlet water temperature is at or below the set point. If so, then the fluid cooler fan is not turned on and all the flow goes through bypass. If the inlet water temperature is above the set point then the fluid cooler fan is turned on at low speed to reduce the exiting water temperature to the set point. If operating the fluid cooler fan at low speed does not reduce the exiting water temperature to the set point, then the fluid cooler fan is increased to its high speed.

The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan at high speed for the entire simulation timestep and fluid cooler fan at low speed for the entire simulation timestep, or fluid cooler fan at low speed for the entire simulation timestep and fluid cooler fan off for the entire simulation timestep). Cyclic losses are not taken into account.

Evaporative fluid coolers consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the evaporative fluid coolers. For this purpose, the last seven input fields can either be provided in the input or if nothing is specified then the default values for these fields will be used. These fields provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a water storage tanks (i.e. WaterUse:Storage objects).

Field: Name

This alpha field contains the identifying name for the fluid cooler.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the fluid cooler's water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the fluid cooler's water outlet node.

Field: Air Flow Rate at High Fan Speed

This numeric field contains the fluid cooler air flow rate at high fan speed in m³/s. A value greater than zero must be defined regardless of fluid cooler performance input method. Alternately, this field can be autosized. See Engineering Reference document for fluid cooler autosizing.

Field: Fan Power at High Fan Speed

This numeric field contains the fan power (in Watts) at the high-speed air flow rate specified in the previous field. A value greater than zero must be specified regardless of fluid cooler performance input method, or this field can be autosized. See Engineering Reference document for fluid cooler autosizing.

Field: Air Flow Rate at Low Fan Speed

This numeric field contains the fluid cooler air flow rate at low fan speed in m³/s. This value must be greater than zero, less than the value specified for the field “Air Flow Rate at High Fan Speed”. This field may be autosized, in which case it is set to 50% of the “Air Flow Rate at High Fan Speed”.

Field: Fan Power at Low Fan Speed

This numeric field contains the fan power (in Watts) at the low-speed air flow rate specified in the previous field. This value must be specified greater than zero or the field may be autosized, in which case it is set to 16% of the “Fan Power at High Fan Speed”.

Field: Design Spray Water Flow Rate

This numeric field contains the design spray water flow rate through the fluid cooler in m³/s. This input field must be specified for all the performance input methods.

Field: Performance Input Method

This alpha field contains the method by which the user will specify fluid cooler performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “StandardDesignCapacity” or “UserSpecifiedDesignCapacity”.

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the fluid cooler. If this field is left blank, the outdoor air conditions entering the fluid cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Field: High-Speed Standard Design Capacity

This numeric input field contains the heat rejection capacity of the fluid cooler in watts, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be 5.382E-8 m³/s per watt of nominal capacity (3 gpm/ton). 125% of this capacity gives the actual fluid cooler heat rejection at these operating conditions (based on historical assumption that the evaporative fluid cooler must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). This field is only used for performance input method = “StandardDesignCapacity”. For other input methods this field is ignored. The standard conditions mentioned above for “standard design capacity” are already specified in the EnergyPlus. So the input fields such as design entering water temp., design entering air wet-bulb and dry-bulb temp. and design water flow rate, if provided in the input, will be ignored for the StandardDesignCapacity performance input method. Also, the standard

conditions are for water as a fluid type so this performance input method can only be used with water as a fluid type (ref. CondenserLoop object).

Field: Low-Speed Standard Design Capacity

This numeric input field contains the heat rejection capacity of the fluid cooler in watts, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be 5.382E-8 m³/s per watt of nominal capacity (3 gpm/ton). 125% of this capacity gives the actual fluid cooler heat rejection at these operating conditions (based on historical assumption that the evaporative fluid cooler must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). This field is only used for performance input method = "StandardDesignCapacity". For other input methods this field is ignored. The standard conditions mentioned above for "standard design capacity" are already specified in the EnergyPlus. So the input fields such as design entering water temp., design entering air wet-bulb and dry-bulb temp. and design water flow rate, if provided in the input, will be ignored for the StandardDesignCapacity performance input method. Also, the standard conditions are for water as a fluid type so this performance input method can only be used with water as a fluid type (ref. CondenserLoop object). The value specified for this field must be greater than zero but less than the value specified for the field "High-Speed Standard Design Capacity".

Field: U-factor Times Area Value at High Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the high speed design air and water flow rates specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a UA value greater than zero but less than or equal to 2,100,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design fluid cooler UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing), the fluid cooler inlet air dry-bulb and wetbulb temperature are taken from the input. This field is only used for performance input method = "UFactorTimesAreaAndDesignWaterFlowRate". For other input methods this field is ignored.

Field: U-factor Times Area Value at Low Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the low speed design air and water flow rates specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a UA value greater than zero but less than or equal to 300,000 and less than the value specified for the field "U-Factor Times Area Value at High Fan Speed" must be defined. This field may be autosized, in which case it is set to 60% of the "U-Factor Times Area Value at High Fan Speed". This field is only used for performance input method = "UFactorTimesAreaAndDesignWaterFlowRate". For other input methods this field is ignored.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the fluid cooler in m³/s. This value is the flow rate of the condenser loop water being cooled by the fluid cooler. This field is ignored for the "StandardDesignCapacity" performance input method. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing).

Field: High-Speed User Specified Design Capacity

This numeric input field contains the heat rejection capacity of the fluid cooler in watts. Design conditions for this capacity i.e. entering air dry-bulb temperature, entering air wet-bulb temperature and entering water temperature must be provided in the input. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

Field: Low-Speed User Specified Design Capacity

This numeric input field contains the heat rejection capacity of the fluid cooler in watts. Design conditions for this capacity i.e. entering air dry-bulb temperature, entering air wet-bulb temperature and entering water temperature must be provided in the input. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

Field: Design Entering Water Temperature

This numeric field contains entering water temperature at nominal conditions in degrees Celsius. The design entering water temperature must be greater than the design entering air temperature. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

Field: Design Entering Air Temperature

This numeric field contains entering air dry-bulb temperature at nominal conditions in degrees Celsius. The design entering air temperature must be greater than the design entering air wet-bulb temperature. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

Field: Design Entering Air Wet-bulb Temperature

This numeric field contains entering air wetbulb temperature at nominal conditions in degrees Celsius. The design entering air wet-bulb temperature must be less than the design entering air (dry-bulb) temperature. Only used for Performance Input Method = UserSpecifiedDesignCapacity; for other performance input methods this field is ignored.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Air Flow Rate at High Fan Speed;
3. Fan Power at High Fan Speed;
4. U-Factor Times Area Value at High Fan Speed;
5. Air Flow Rate at Low Fan Speed;
6. Fan Power at Low Fan Speed;
7. U-Factor Times Area Value at Low Fan Speed;

Note that the U-Factor Times Area Value at High Fan Speed is not multiplied by the Sizing Factor. Instead the design evaporative fluid cooler load is multiplied by the sizing factor and the design UA then calculated as usual. The U-Factor Times Area Value at Low Fan Speed is set to 60% of the full load design UA.

Field: Evaporation Loss Mode

This field is used to choose which method is used to model the amount of water evaporated by the evaporative fluid cooler. There are two options: LossFactor or SaturatedExit. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the evaporative fluid cooler is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the evaporative fluid cooler model (and does not require additional user input).

Field: Evaporation Loss Factor

This field is used to specify the rate of water evaporated from the evaporative fluid cooler and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to LossFactor. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Empirical correlation is used to calculate default loss factor if it not explicitly specified in the input file.

Field: Drift Loss Percent

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value.

Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options ConcentrationRatio or ScheduledRate. The choice will determine which of the two models below is used. The default is ConcentrationRatio.

Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the evaporative fluid cooler as a function of the rate of evaporation. Blowdown is water intentionally drained from the evaporative fluid cooler in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value.

Field: Blowdown Makeup Water Usage Schedule Name

This alpha field contains the name of the schedule used to define the amount of water (m³/s) flushed from the basin on a periodic basis to purge the evaporative fluid cooler of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation Mode is set to ScheduledRate. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Default value is under investigation for now cooling tower's evaporation loss factor is taken as default value. This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the evaporative fluid cooler is active and water is flowing through the evaporative fluid cooler (regardless of the water usage defined by this schedule).

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the evaporative fluid cooler obtains water used for evaporative cooling. If blank or omitted, then the evaporative fluid cooler will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the evaporative fluid cooler will obtain its water from that tank. If a tank is specified, the evaporative fluid cooler will attempt to obtain all the water it uses from the tank. However if

the tank cannot provide all the water the evaporative fluid cooler needs, then the evaporative fluid cooler will still operate and obtain the rest of the water it needs from the mains (referred to as 'Starved' water).

Examples of an IDF specification for this object are shown below:

Evaporative Fluid Cooler Fan Electric Power [W]

The average electric power consumption of the fluid cooler fan in Watts for the timestep being reported.

Evaporative Fluid Cooler Fan Electric Consumption [J]

Fan energy use in Joules. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Evaporative Fluid Cooler Heat Transfer [W]

This is the average rate, in Watts, at which heat is removed from the condenser water loop by the fluid cooler for the time step being reported.

Evaporative Fluid Cooler Water Inlet Temperature [C]

The fluid temperature at the fluid cooler inlet in degrees Celsius.

Evaporative Fluid Cooler Water Outlet Temperature [C]

The fluid temperature at the fluid cooler outlet in degrees Celsius.

Evaporative Fluid Cooler Water Mass Flow Rate [kg/s]

The average fluid mass flow rate through the fluid cooler in kg/s for the time step being reported.

Evaporative Fluid Cooler Water Make Up Rate [m³/s]***Evaporative Fluid Cooler Water Make Up [m³]***

These outputs are the external spray water consumed by the evaporative fluid cooler. This is the total of evaporation, drift, and blowdown.

Evaporative Fluid Cooler Water Evaporation Rate [m³/s]***Evaporative Fluid Cooler Water Evaporation [m³]******Evaporative Fluid Cooler Water Drift Rate [m³/s]******Evaporative Fluid Cooler Water Drift [m³]******Evaporative Fluid Cooler Water Blowdown Rate [m³/s]******Evaporative Fluid Cooler Water Blowdown [m³]***

These outputs provide the breakdown of the different components of water use during fluid cooler operation.

Evaporative Fluid Cooler Water Make Up Mains Draw [m³]

The volume of make up water provided by the mains in cubic meters. If no Supply Water Storage Tank is specified, then all fluid cooler make up water is provided by the mains (same as Evaporative Fluid Cooler Water Make Up). If a Supply Water Storage Tank is specified, then the make up from the mains only occurs when sufficient water supply is not available from the tank (same as Evaporative Fluid Cooler Water Starved by Storage Tank). This output variable is metered on HeatRejection:MainsWater, MainsWater:Plant and MainsWater:Facility.

Evaporative Fluid Cooler Water From Storage Tank Rate [m³/s]***Evaporative Fluid Cooler Water From Storage Tank [m³]***

These are the rate and volume of water provided by the Supply Water Storage Tank.

Evaporative Fluid Cooler Water Starved By Storage Tank Rate [m³/s]***Evaporative Fluid Cooler Water Starved By Storage Tank [m³]***

These are the rate and volume of water the Supply Water Storage Tank was not able to provide. The starved water is assumed to come from the mains. The fluid cooler's operation is not affected by a lack of storage tank water.

FluidCooler:SingleSpeed

Fluid coolers are components that may be assigned to condenser loops. The Fluid cooler is modeled as a cross flow heat exchanger (both streams unmixed) with single-speed fans (induced draft configuration). The user must define fluid cooler performance via one of the two methods: design heat transfer coefficient-area product (UA) and design water flow rate, or nominal fluid cooler capacity at a specific rating point. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified.

The fluid cooler seeks to maintain the temperature of the water exiting the fluid cooler at (or below) a set point. The set point schedule value is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the CondenserLoop object. The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan on for the entire simulation timestep and fluid cooler fan off for the entire simulation timestep). Cyclic losses are not taken into account.

Field: Name

This alpha field contains the identifying name for the Fluid Cooler.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the Fluid Cooler’s water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the Fluid Cooler’s water outlet node.

Field: Performance Input Method

This alpha field contains the method by which the user will specify fluid cooler performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”.

Field: U-factor Times Area Value at Design Air Flow Rate

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the design air and water flow rates specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design fluid cooler UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing), the fluid cooler inlet air dry-bulb and wetbulb temperature are taken from the input. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the fluid cooler UA based on the fluid cooler capacity and nominal conditions specified in input file.

Field: Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the fluid cooler in watts, Nominal conditions i.e. entering air dry-bulb temperature, entering air wet-bulb temperature and Entering water temperature should be provided in the input.

Field: Design Entering Water Temperature

This numeric field contains entering water temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering water temperature must be greater than the design entering air temperature.

Field: Design Entering Air Temperature

This numeric field contains entering air dry-bulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air temperature must be greater than the design entering air wet-bulb temperature.

Field: Design Entering Air Wet-bulb Temperature

This numeric field contains entering air wetbulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air wet-bulb temperature must be less than the design entering air (dry-bulb) temperature.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the fluid cooler in m³/s. This value is the flow rate of the condenser loop water being cooled by the fluid cooler. A water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing).

Field: Design Air Flow Rate

This numeric field contains the design air flow rate induced by the fluid cooler fan in m³/s. A value greater than zero must be defined regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering Reference document for fluid cooler autosizing.

Field: Fan Power at Design Air Flow Rate

This numeric field contains the fan power (in watts) at the design air flow rate specified in the previous field. A value greater than zero must be specified regardless of the performance input method, or this field can be autosized. See Engineering ref. for fluid cooler autosizing.

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the fluid cooler. If this field is left blank, the outdoor air conditions entering the fluid cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

An IDF specification for this object is shown below:

```

HVAC,Average,Fluid Cooler Water Outlet Temp [C]
HVAC,Average,Fluid Cooler Water Mass Flow Rate [kg/s]
```

Fluid Cooler Fan Electric Power [W]

The electric power consumption of the fluid cooler fans.

Fluid Cooler Fan Electric Consumption [J]

Fan energy use. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Fluid Cooler Heat Transfer [W]

This is the rate at which heat is removed from the condenser water loop by the fluid cooler.

Fluid Cooler Water Inlet Temperature [C]

The loop temperature at the fluid cooler inlet.

Fluid Cooler Water Outlet Temperature [C]

The loop temperature at the fluid cooler outlet.

Fluid Cooler Water Mass Flow Rate [kg/s]

The loop mass flow rate of the circulating condenser water loop.

FluidCooler:TwoSpeed

The two-speed fluid cooler is modeled in a similar fashion to the single-speed fluid cooler. The fluid cooler is modeled as a cross flow heat exchanger (both stream unmixed) with two-speed fans (induced draft configuration). The user must define fluid cooler performance via one of two methods: heat transfer coefficient-area product (UA) and design water flow rate, or nominal fluid cooler capacity at a specific rating point. Regardless of which method is chosen, the airflow rate and corresponding fan power at both high and low fan speed must be specified. The Fluid Cooler seeks to maintain the temperature of the water exiting the Fluid Cooler at (or below) a set point. The set point schedule is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the CondenserLoop object. The model first runs at low speed and calculates the fluid cooler exiting water temperature. If the exiting water temperature based on “low speed” is at or below the set point, then the fluid cooler fan runs at this speed or below this speed. If the exiting water temperature remains above the set point after “low speed” is modeled, then the fluid cooler fan runs at high speed to reduce the exiting water temperature.

The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan at high speed for the entire simulation timestep and fluid cooler fan at low speed for the entire simulation timestep.). Cyclic losses are not taken into account.

Field: Name

This alpha field contains the identifying name for the fluid cooler.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the fluid cooler's water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the fluid cooler's water outlet node.

Field: Performance Input Method

This alpha field contains the method by which the user will specify fluid cooler performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”.

Field: U-factor Times Area Value at High Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the high-speed air flow rate and design water flow rate specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the fluid cooler UA value at high fan speed is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing), fluid cooler water inlet

temperature, fluid cooler inlet air drybulb and wetbulb are provided in the input. If "Performance Input Method" is specified as "NominalCapacity", then this field must be left blank since the model automatically calculates the fluid cooler UA based on the capacity specified in the field "High Speed Nominal Capacity" and nominal conditions.

Field: U-factor Times Area Value at Low Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the design water flow rate and low-speed air flow rate specified above. If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", this value must be greater than zero but less than or equal to 300,000, less than the value specified for the field "U-factor Times Area Value at High Fan Speed". This field may be autosized, in which case it is set to 60% of the "U-factor Times Area Value at High Fan Speed". If "Performance Input Method" is specified as "NominalCapacity", then this field must be left blank since the model automatically calculates the fluid cooler UA based on the fluid cooler capacity specified in the field "Low Speed Nominal Capacity".

Field: High Speed Nominal Capacity

This numeric input field contains the "nominal" heat rejection capacity of the fluid cooler in watts under high-speed fan operation, with nominal (design) inputs entering water temperature, entering air temperature and entering air wet-bulb temperature. The design water flow rate is also provided in the input.

Field: Low Speed Nominal Capacity

This numeric input field contains the "nominal" heat rejection capacity of the Fluid Cooler in watts under low-speed fan operation, with nominal (design) inputs entering water temperature, entering air temperature and entering air wet-bulb temperature. The design water flow rate is also provided in the input. The value specified for this field must be greater than zero but less than the value specified for the field "High Speed Nominal Capacity".

Field: Design Entering Water Temperature

This numeric field contains entering water temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering water temperature must be greater than the design entering air temperature.

Field: Design Entering Air Temperature

This numeric field contains entering air dry-bulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air temperature must be greater than the design entering air wet-bulb temperature.

Field: Design Entering Air Wet-bulb temperature

This numeric field contains entering air wet-bulb temperature at nominal conditions in degrees Celsius. This field must be specified for both the performance input methods. The design entering air wet-bulb temperature must be less than the design entering air (dry-bulb) temperature.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the fluid cooler in m^3/s . This value is the flow rate of the condenser loop water being cooled by the fluid cooler. A water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Sizing and Input for Design Calculations and Component Autosizing).

Field: Air Flow Rate at High Fan Speed

This numeric field contains the fluid cooler air flow rate at high fan speed in m³/s. A value greater than zero must be defined regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering ref. for fluid cooler autosizing.

Field: Fan Power at High Fan Speed

This numeric field contains the fan power (in Watts) at the high-speed air flow rate specified in the previous field. A value greater than zero must be specified regardless of the fluid cooler performance input method, or this field can be autosized. See Engineering ref. for fluid cooler autosizing.

Field: Air Flow Rate at Low Fan Speed

This numeric field contains the fluid cooler air flow rate at low fan speed in m³/s. This value must be greater than zero, less than the value specified for the field “Air Flow Rate at High Fan Speed”. This field may be autosized, in which case it is set to 50% of the “Air Flow Rate at High Fan Speed”.

Field: Fan Power at Low Fan Speed

This numeric field contains the fan power (in Watts) at the low-speed air flow rate specified in the previous field. This value must be specified greater than zero or the field may be autosized, in which case it is set to 16% of the “Fan Power at High Fan Speed”.

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the Fluid Cooler. If this field is left blank, the outdoor air conditions entering the Fluid Cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Examples of an IDF specification for this object are shown below:

HVAC,Average,Fluid cooler Heat Transfer [W]
HVAC,Average,Fluid cooler Water Inlet Temp [C]
HVAC,Average,Fluid cooler Water Outlet Temp [C]
HVAC,Average,Fluid cooler Water Mass Flow Rate [kg/s]

Fluid Cooler Fan Electric Power [W]

Average fan electric power consumed.

Fluid Cooler Fan Electric Consumption [J]

Total energy used by the fan. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Fluid Cooler Heat Transfer [W]

This is the rate at which heat is removed from the condenser water loop by the fluid cooler.

Fluid Cooler Water Inlet Temperature [C]

Loop temperature at the fluid cooler inlet.

Fluid Cooler Water Outlet Temperature [C]

Loop temperature at the fluid cooler outlet.

Fluid Cooler Water Mass Flow Rate [kg/s]

Loop mass flow rate through the fluid cooler.

GroundHeatExchanger:Vertical

The Energy Plus Ground loop heat exchanger is a condenser component. This serves the condenser supply side in addition to the cooling towers and other condensing components. The following figure shows the Ground Heat Exchanger in the Energy Plus simulation environment.

The heat exchanger response is defined by a G-function. This is a non-dimensional function that is used to calculate the response to square heat pulses of different duration. (This function is not the same as 'G-factors' referred to in the ASHRAE Applications Handbook). This continuous function is specified by a series of data pairs (LNTTS_i, GFNC_i) where,

- LNTTS_i is the non-dimensional time: $\ln(T/T_s)$
- GFNC_i is the G-function value

The G-function is different for each borehole field configuration (i.e. a 4x4 field has a different response than a 80x80 field) and the borehole thermal resistance. It is also dependant on the ratio of borehole spacing to depth. G-function values, for accurate simulation, have to be calculated for each specific heat exchanger design. This can be done using some commercial ground loop heat exchanger design tool and the like. A reference data set, containing examples input data for 1x2, 4x4 and 8x8 configurations and for both standard and thermally enhanced grout, have also been provided. These data are provided as examples only.

Further details of the implementation of this model can be found in:

Murugappan, A. *Implementing Ground Source Heat Pump and Ground Loop Heat Exchanger Models in the EnergyPlus Simulation Environment*. M.S. Thesis, Oklahoma State University, December 2002.

Figure 72. Schematic of EnergyPlus Ground Loop Heat Exchanger

The data definition for the ground loop heat exchanger from the Energy+.idd is shown below. The syntax to the specification of Borehole, U-tube and ground are illustrated in the example following.

Field: Name

This alpha field contains the identifying name for the ground heat exchanger (GHE).

Field: Inlet Node Name

This alpha field contains the ground heat exchanger inlet node name.

Field: Outlet Node Name

This alpha field contains the ground heat exchanger outlet node name.

Field: Maximum Flow Rate

This numeric field contains the GHE maximum design flow rate in cubic meters per second {m³/s}.

Field: Number of Bore Holes

This numeric field contains the number of bore holes in the GHE installation.

Field: Bore Hole Length

This numeric field contains the length of the borehole in meters {m}.

Field: Bore Hole Radius

This numeric field contains the radius of the borehole in meters.

Field: Ground Thermal Conductivity

This numeric field contains the thermal conductivity of the ground in W/m-K.

FieldSet: Ground Thermal Heat Capacity

This numeric field contains the thermal heat capacity of the ground in J/m³-K.

Field: Ground Temperature

This numeric field contains the far field temperature of the ground in °C.

Field: Design Flow Rate

This numeric field contains the design volume flow rate of the GHE in m³/s.

Field: Grout Thermal Conductivity

This numeric field contains the thermal conductivity of the filler material in W/m-K.

Field: Pipe Thermal Conductivity

This numeric field contains the thermal conductivity of the pipe in W/m-K.

Field: Pipe Out Diameter

This numeric field contains the outer diameter of the U-tube (pipe) in meters {m}.

Field: U-Tube Distance

This numeric field contains the distance between the two legs of the U-tube in meters {m}.

Field: Pipe Thickness

This numeric field contains the outer diameter of the U-tube (pipe) in meters.

Field: Maximum Length of Simulation

This numeric field contains the maximum number of years of simulation to be carried out.

Field: G-Function Reference Ratio

The G-Functions may be formulated slightly differently based on the program which generated them. The “raw” G-Functions are based on an borehole radius to active length ratio of 0.0005. If the physical ratio is different from this, a correction must be applied. EnergyPlus will apply the correction, based on the reference ratio entered in this field. Therefore, therefore two possible input configurations.

- If the G-Functions have not had a correction applied, then the G-Functions are still based on a reference of 0.0005, so use a value of 0.0005 in this field. EnergyPlus will adjust the G-Functions internally to create the properly referenced G-Function.
- If the correction has already been applied, then the input G-Functions are based on a reference to the actual (physical) radius/length ratio, so enter the physical radius/length in this field. Entering the actual value will nullify any internal corrections, which will avoid re-basing the G-Function set.

The software GLHEPro has been making this “pre-correction” to the data sets since version 3.1 of that software, so this input field should match the actual (physical) radius/length ratio.

Field: Number of Data Pairs of the G Function

The borehole response is defined by a non-dimensional ‘G-function’. This is specified as a series of data points giving values of non-dimensional time vs G-function value (LNTTS1, GFUNC1), (LNTTS2, GFUNC2), (LNTTS3, GFUNC3) (LNTTS n , GFUNC n). This numeric field contains the number of data pairs to be read in (n).

Field: G-Function $\ln(T/T_s)$ Value <x>

This numeric field contains the natural log of time/steady state time: $\ln(T/T_s)$

Field: G-Function 'G' Value <x>

This numeric field contains the G-function value of the corresponding LNTTS.

The following is an example input:

GroundHeatExchanger:Pond

The pond heat exchanger model represents a shallow pond with submerged hydronic tubes through which the heat transfer fluid is circulated. The model represents a 'shallow' pond in that no attempt is made to model any stratification effects that may be present in deeper ponds.

This type of heat exchanger is intended to be connected to the supply side of a condenser loop, and can be used with any type of plant loop. The pond may be specified as the only heat exchanger on the condenser loop (as shown in Figure 73) or it may be connected in parallel with other condenser loop heat exchangers (such as cooling towers, ground surface heat exchangers) as shown in the second figure below.

Figure 73. Example of Pond Ground Heat Exchanger as only heat exchanger on condenser loop

Figure 74. Pond Ground Heat Exchanger with other heat exchangers on condenser loop

Field: Name

This alpha field contains the identifying name for the outside pond heat exchanger.

Field: Fluid Inlet Node Name

This alpha field contains the fluid inlet node name.

Field: Fluid Outlet Node Name

This alpha field contains the fluid outlet node name.

Field: Pond Depth

This numeric field contains the pond depth {m}.

Field: Pond Area

This numeric field contains the pond area {m²}.

Field: Hydronic Tubing Inside Diameter

This numeric field contains the hydronic tubing inside diameter {m}.

Field: Hydronic Tubing Outside Diameter

This numeric field contains the hydronic tubing outside diameter {m}.

Field: Hydronic Tubing Thermal Conductivity

This numeric field contains the hydronic tubing thermal conductivity in W/mK.

Field: Ground Thermal Conductivity

This numeric field contains the ground thermal conductivity in W/m²K.

Field: Number of Tubing Circuits

This numeric field contains the number of hydronic tubing circuits, total in parallel in this pond..

Field: Length of Each Tubing Circuit

This numeric field contains length {m} of each hydronic tubing circuit.

An example of the IDF is shown below.

```

These outputs are the pond fluid inlet and outlet temperatures and mass flow rate.

Pond Ground Heat Exchanger Bulk Temp [C]

This output is the pond bulk temperature.

GroundHeatExchanger:Surface

The surface heat exchanger model is to simulate hydronic surface ground heat exchangers. This includes pavement surfaces with embedded pipes for snow-melting or heat rejection from hybrid ground source heat pump systems.

The heat exchanger may be ground coupled or not. In the latter case the bottom surface is exposed to the wind but not solar gains. This type of heat exchanger is intended to be connected to the supply side of a condenser loop, and can be used with any type of plant loop. The surface heat exchanger may be specified as the only heat exchanger on the condenser loop (as shown in the first figure below) or it may be connected in parallel with other condenser loop heat exchangers (such as cooling towers, ground surface heat exchangers) as shown in the second figure below.

Figure 75. Example of Surface Ground Heat Exchanger as only heat exchanger on condenser loop

Figure 76. Surface Ground Heat Exchanger with other heat exchangers on condenser loop

Field: Name

This alpha field contains the identifying name for the outside panel heat exchanger.

Field: Construction Name

This alpha field contains the construction name. It must contain a valid “Construction” name that is usual for Surfaces. (Ref: Group – Surface Construction Elements).

Field: Fluid Inlet Node Name

This alpha field contains the fluid inlet node name.

Field: Fluid Outlet Node Name

This alpha field contains the fluid outlet node name.

Field: Hydronic Tubing Inside Diameter

This numeric field contains the hydronic tubing inside diameter in m.

Field: Number of Tubing Circuits

This numeric field contains the number of hydronic tubing circuits.

Field: Hydronic Tube Spacing

This numeric field contains the hydronic tube spacing in m.

Field: Surface Length

This numeric field contains the surface length in m.

Field: Surface Width

This numeric field contains the surface width in m.

Field: Lower Surface Environment

This alpha field expresses the lower surface exposure: Exposed or Ground.

An example of this statement in an IDF is shown below:

```

Surface Ground Heat Exchanger Heat Transfer Rate [W]

Surface Ground Heat Exchanger Surface Heat Transfer Rate [W]

Surface Ground Heat Exchanger Energy [J]

These outputs are the source heat transfer rate, surface heat transfer rate and the total source energy input for the timestep.

Surface Ground Heat Exchanger Mass Flow Rate [kg/s]

Surface Ground Heat Exchanger Inlet Temp [C]

Surface Ground Heat Exchanger Outlet Temp [C]

These outputs are the surface heat exchanger fluid inlet and outlet temperatures and mass flow rate.

Surface Ground Heat Exchanger Top Surface Temp [C]

Surface Ground Heat Exchanger Bottom Surface Temp [C]

These outputs are the surface heat exchanger top and bottom surface temperatures.

Surface Ground Heat Exchanger Top Surface Flux [J/m²]

Surface Ground Heat Exchanger Bottom Surface Flux [J/m²]

These outputs are the surface heat exchanger top and bottom surface flux.

Surface Ground Heat Exchanger Surface Energy [J]

This is the total surface energy exchange for the timestep.

Surface Ground Heat Exchanger Source Temp [C]

This is the surface heat exchanger source temperature.

HeatExchanger:Hydronic

This component is intended to be used in a condenser loop to simulate the effect of coupling the condenser and plant loops directly. For example, to bypass a chiller and couple the chilled water loop to the condenser loop so that the chilled water loop uses a cooling tower as

its cooling source. This component is accordingly connected to both plant and condenser water loops (in a similar way to a chiller). The component acts to switch on and off the specified chiller/heat pump according to specified criteria (either a setpoint schedule, outside drybulb or wetbulb temperatures). The heat exchanger may be operated either in ideal or UA-effectiveness mode. In the UA-effectiveness mode the actual heat transfer between loops is calculated according to the UA-effectiveness method assuming counter flow. In ideal mode the maximum possible heat transfer is calculated. In this case, if both fluids are the same type and the loop flow rates are the same, operation is if the loops are directly coupled.

The specified plant component (chiller) is switched off and coupling enabled when either the drybulb, wetbulb or condenser loop temperature falls below the scheduled temperature. Any setpoint schedule can be specified. The usual way to operate a chiller would be to specify the schedule the same as the chilled water loop temperature and operate in 'loop' mode. In this way the loops would be connected when condenser water was available at or below the chilled water temperature.

Field: Name

This alpha field contains the unique identifying name of this component.

Field: Controlled Component Name

This alpha field contains the unique identifying name of the component under the control of the heat exchanger (e.g. the corresponding chiller).

Field: Controlled Component Object Type

This alpha filed contains the 'type' of the component under the control of the heat exchanger (e.g. Chiller:ConstantCOP).

Field: Setpoint Schedule Name

This alpha field contains the name of the setpoint schedule that is being used to control the heat exchanger.

Field: Condenser Inlet Node Name

This alpha field contains the name of the inlet node on the condenser loop.

Field: Condenser Outlet Node Name

This alpha field contains the name of the outlet node on the condenser loop.

Field: Plant Inlet Node Name

This alpha field contains the name of the inlet node on the plant loop.

Field: Plant Outlet Node Name

This alpha field contains the name of the outlet node on the plant loop.

Field: Free Cooling Control Mode

This alpha field determines the control mode. Free cooling (coupling) is enabled depending on the comparison of the scheduled temperature with the temperature defined here (drybulb, wetbulb or condenser loop). For example, specifying outside wetbulb here, free cooling would be enabled if the wetbulb temperature fell below the scheduled temperature. Options are: **DryBulbTemperature**, **WetBulbTemperature**, **Schedule**, or **Loop**. The default is Loop.

Field: Heat Exchanger Setpoint Schedule Name

This alpha field contains the name of the setpoint schedule for the heat exchanger.

Field: Heat Exchange Mode

The heat exchanger can operate as either an ideal heat exchanger (the max possible energy is transferred across the loops) or as specified by the UA and effectiveness. The options are

correspondingly **Ideal** and **UFactorTimesAreaEffectiveness**. Effectiveness is calculated assuming counter-flow. The default is Ideal.

Field: U-Factor Times Area Value

This numerical field is used to specify the overall UA {W/K} for use in the calculation of actual heat transfer when in UFactorTimesAreaEffectiveness mode.

Field: Condenser Side Flow Rate

This numerical field is used to specify the design flow rate {m³/s} of this component on the condenser side. This would normally be the same as the loop/cooling tower flow rate.

Field: Plant Side Flow Rate

This numerical field is used to specify the design flow rate {m³/s} of this component on the plant side. This would normally be the same as the loop/chiller flow rate.

Field: Controlled Component Condenser Inlet Node Name

This alpha field contains the name of the inlet node on the condenser loop for the component being controlled by the heat exchanger.

Field: Controlled Component Condenser Outlet Node Name

This alpha field contains the name of the outlet node on the condenser loop for the component being controlled by the heat exchanger.

Field: Controlled Component Plant Inlet Node Name

This alpha field contains the name of the inlet node on the plant loop for the component being controlled by the heat exchanger.

Field: Controlled Component Plant Outlet Node Name

This alpha field contains the name of the outlet node on the plant loop for the component being controlled by the heat exchanger.

An example of the model's input from an idf file is shown below.

Status of the heat exchanger, 1 represents on, 0 represents off.

HeatExchanger:Plate

This component is intended to couple two condenser loops, so that the effect of connecting heating/cooling equipments in series in a branch can be achieved, as is the case required by some hybrid systems. The component is connected to the supply side of one condenser loop and to the demand side of the second condenser loop. The coupling and uncoupling of two loops is achieved based on control equipment defined in the input file. The heat exchanger can be a single component on a branch or can be connected to any other condenser equipment. The heat transfer is calculated as in the case of hydronic free cooling heat exchanger. The figure below shows a typical hybrid system, which uses a Plate heat exchanger to couple two condenser loops.

Figure 77. Plate Heat Exchanger (hybrid)

Field: Name

This alpha field contains the unique identifying name of this component.

Field: Controlled Component Name

This alpha field is the name of the component, which allows the plate heat exchanger to decide whether the loops have to be coupled or not. If this component is ON, the loops are coupled else the loops are uncoupled.

Field: Controlled Component Object Type

This alpha field tells the type of the component with the name given in the previous field.

Field: Demand Side Inlet Node Name

This alpha field contains the name of the inlet node on the condenser demand side connected to the heat exchanger.

Field: Demand Side Outlet Node Name

This alpha field contains the name of the outlet node on the condenser demand side connected to the heat exchanger.

Field: Supply Side Inlet Node Name

This alpha field contains the name of the inlet node on the Condenser supply side connected to the heat exchanger.

Field: Supply Side Outlet Node Name

This alpha field contains the name of the outlet node on the Condenser supply side connected to the heat exchanger.

Field: Heat Exchange Mode

The heat exchanger can operate as either an ideal heat exchanger (the max possible energy is transferred across the loops) or as specified by the UA and effectiveness. The options are

correspondingly **Ideal** and **UFactorTimesAreaEffectiveness**. Effectiveness is calculated assuming counter-flow. The default is Ideal.

Field: U-Factor Times Area Value

This numerical field is used to specify the overall UA for use in the calculation of actual heat transfer when in UFactorTimesAreaEffectiveness mode.

Field: Demand Side Flow Rate

This numerical field is used to specify the design flow rate of this component on the Demand side. This would normally be the same as the loop/cooling tower flow rate.

Field: Supply Side Flow Rate

This numerical field is used to specify the design flow rate of this component on the Supply side. This would normally be the same as the loop flow rate.

An example of the model's input from an idf file is shown below.

Plate Heat Exchanger Heat Transfer Rate [W]

The heat transfer rate between the loops connected via the heat exchanger.

Plate Heat Exchanger Demand Side Mass Flow rate [kg/s]

Plate Heat Exchanger Supply Side Mass Flow rate [kg/s]

The flow rates in each loop.

Plate Heat Exchanger Demand Side Inlet Temp[C]

Plate Heat Exchanger Demand Side Outlet Temp[C]

Plate Heat Exchanger Supply Side Inlet Temp[C]

Plate Heat Exchanger Supply Side Outlet Temp[C]

The inlet and outlet temperatures on each side of the component.

HeatExchanger:WatersideEconomizer

The heat exchanger model designed primarily to support the simulation of plant waterside economizers, but is also suitable for other plant applications. Three types of heat exchangers

can be selected: 1.) Plate frame, 2.) Single pass counter-flow and 3.) Single pass parallel-flow. The heat transfer rate is calculated using the UA-effectiveness method. An appropriate effectiveness-NTU correlation is used for each type of heat exchanger. The maximum possible heat transfer rate can be used in the simulation by specifying an **Ideal** heat exchanger. For this case an effectiveness of 1.0 is used.

Field: Name

This alpha field contains the unique identifying name of this component.

Field: Heat Exchanger Type

This alpha field identifies the type of heat exchanger. Heat exchanger type is specified by one of the following key words:

PlateFrame: specifies a plate-frame heat exchanger. The effectiveness will be calculated using a plate frame heat exchanger correlation. Currently this type of heat exchanger is approximated as cross flow with both streams unmixed

CounterFlow: specifies a counter-flow shell and tube heat exchanger. The effectiveness will be calculated using a counter-flow shell and tube heat exchanger correlation.

ParallelFlow: specifies a parallel-flow shell and tube heat exchanger. The effectiveness will be calculated using a parallel-flow shell and tube heat exchanger correlation.

Ideal: specifies an ideal heat exchanger. The effectiveness will be set to '1.0' and the specified UA will be ignored. The heat transfer rate will be calculated as the maximum possible heat transfer rate.

Field: Availability Schedule Name

Name of the availability schedule for this heat exchanger.

Field: Chilled Water Inlet Node Name

This alpha field contains the name of the heat exchanger inlet node connected to chilled water . In typical water side economizer applications this is the Plant loop.

Field: Chilled Water Outlet Node Name

This alpha field contains the name of the heat exchanger outlet node connected to chilled water . In typical water side economizer applications this is the Plant loop.

Field: Condenser Inlet Node Name

This alpha field contains the name of the heat exchanger inlet node connected to the condenser . In typical water side economizer applications this is the Condenser loop.

Field: Condenser Outlet Node Name

This alpha field contains the name of the heat exchanger outlet node connected to the condenser . In typical water side economizer applications this is the Condenser loop.

Field: Chilled Water Side Maximum Flow Rate

This numerical field is used to specify the design (maximum) flow rate {m³/s} for the side of the heat exchanger connected to chilled water loop.

Field: Condenser Side Maximum Flow Rate

This numerical field is used to specify the design (maximum) flow rate {m³/s} for the side of the heat exchanger connected to the Condenser Loop.

Field: Heat Exchanger U-Factor Times Area Value

This numerical field is used to specify the overall U-Factor Times Area (UA) {W/K} for use in the calculation of the heat exchanger effectiveness using the appropriate Δ-NTU correlation. If **Ideal** is specified as the heat exchanger type, the effectiveness will be set to 1.0. When set

to autosize Heat Exchanger U-Factor Times Area Value is calculated based on an effectiveness of 1.0

Field: Minimum Temperature Difference to Activate Heat Exchanger

This numerical field is the minimum temperature difference between chilled water side heat exchanger inlet and condenser side heat exchanger inlet required to turn on heat exchanger.

An example of the model's input from an idf file is shown below.

```
HeatExchanger:WatersideEconomizer,

Economizer Heat Exchanger Plant Side Inlet Temp[C]

Economizer Heat Exchanger Plant Side Outlet Temp[C]

The inlet and outlet temperatures on each side of the component.

Group – Plant-Condenser Flow Control

The connector list described earlier determines how the branches of a particular loop will be hooked together. These connections can be classified either as a separation of a single stream into several outlet streams (splitter) or the merging of several streams into a single outlet stream (mixer). Due to the limitation per branch of a single splitter and a single mixer, the connector list can only have two pieces of equipment as a maximum. The names defined for either/both the splitter or/and the mixer refer then to "component" definitions as described below.

Connector:Splitter, Connector:Mixer

The format of both the **Connector:Splitter** and **Connector:Mixer** statements is similar. Both begin with an identifying name followed by the branch name of the "single side" of the

component. In the case of the splitter, this is the inlet since the inlet stream is broken into several outlet streams. In the case of the mixer, this is the outlet since several streams are mixed together to form a single outlet. The remaining list of up to 50 names is simply the branch names of the outlet legs in the case of the splitter and inlet legs in the case of the mixer. No control logic is assumed in these components—a determination of how much air to split in which direction using the splitter must be defined by other components.

Connector:Splitter

Field: Name

This alpha field contains the identifying name for the Splitter.

Field: Inlet Branch Name

This alpha field contains the identifying name for the Splitter Inlet Branch.

Field: Outlet Branch <x> Name

This alpha field contains the identifying names for the Splitter Outlet Branches and you enter as many outlet branches as needed.

Connector:Mixer

Field: Name

This alpha field contains the identifying name for the Mixer.

Field: Outlet Branch Name

This alpha field contains the identifying name for the Mixer Outlet Branch.

Field: Inlet Branch <x> Name

This alpha field contains the identifying names for the Mixer Inlet Branches and you enter as many inlet branch names as needed..

An example of these statements in an IDF is:

```
Connector:Splitter,
    CW Loop Splitter,
    CW Pump Branch,
    Little Chiller Branch,
    Big Chiller Branch,
    Purchased Cooling Branch,
    Supply Bypass Branch;
Connector:Mixer,
    CW Loop Mixer,
    Cooling Supply Outlet,
    Little Chiller Branch,
    Big Chiller Branch,
    Purchased Cooling Branch,
    Supply Bypass Branch;
```

TemperingValve

This object is used for special cases where plant flow control is needed to make efficient use of thermal storage. In certain solar hot water and heat recovery situations, a thermal storage tank may become warmer than is necessary or allowable for safe use of the hot water. Although real installations of a tempering, or anti-scald valve, would more commonly mix a new stream of mains water with the hot water to achieve a desired outlet temperature, this is difficult to model directly within EnergyPlus because plant loops need to be closed circuits. For many installations where the water entering the splitter is directly from the mains, such as make up water entering a water heater tank, the modeling provided with this object should be thermodynamically equivalent.

The TemperingValve object models a temperature-controlled diversion valve. It models a valve on a bypass pipe that can open to divert flow around one or more plant components. It can only be used on one of two branches between a Splitter and a Mixer. The figure below shows the use of the tempering valve with a Water Heater:Mixed component on "Stream 2." The tempering valve acts to divert flow through the branch it is on in order to adjust the temperature at the outlet of the mixer. If the temperature at Stream 2 Source Node is warmer than the setpoint and the inlet flow is cooler than the setpoint, then a controller determines how much flow should bypass the storage tank to achieve the desired setpoint.

Figure 78. Tempering Valve Schematic

The TemperingValve is an **Active** component and the other path should have only **Passive** components. Only two paths in the splitter/mixer can be used; bypasses are not allowed. No other Connector:Splitter and Connector:Mixer pair can be used on the supply side of the plant loop.

Field: Name

This field should contain an unique name for each TemperingValve object

Field: Inlet Node Name

This field should contain the name of node which is the inlet for the valve.

Field: Outlet Node Name

This field should contain the name of node which is the outlet for the valve

Field: Stream 2 Source Node Name

This field should contain the name of node that is the inlet to the Mixer object for the second stream containing the component whose flow is being diverted.

Field: Temperature Setpoint Node Name

This field should contain the name of a node that has a temperature setpoint assigned to it. A separate set point manager object is needed to provide a set point on the node listed here.

Field: Pump Outlet Node Name

This field should contain the name of the node that is the outlet for the pump that is one the same plant loop. This node is used to sense the total flow rate.

This object is demonstrated in the example file called SolarCollectorFlatPlateWater.idf. An example of this object is:

```
TemperingValve,
    DHW Anti-Scald Diverter,
    DHW Anti-Scald Inlet Node, ! Inlet Node Name
    DHW Anti-Scald Outlet Node, ! Outlet Node Name
    SHW Storage Tank Use Outlet Node, ! Stream 2 Source Node Name
    DHW Instantaneous Boost Outlet Node, ! Temperature Setpoint Node Name
    DHW Use Side Pump Outlet; ! pump outlet node
```

Tempering Valve Outputs

Use report variables for System Nodes for flow and temperature results.

Group – Air Distribution

AirLoopHVAC

Air loops along with zone equipment form the entire forced air heating and cooling system (air side). The main statement for defining an air loop is the *AirLoopHVAC* object described here. As with the main plant and condenser statements, several of the items in the *AirLoopHVAC* object definition are actually names that refer to other objects in the input file. After the *AirLoopHVAC* object name, four such list pointers are encountered: for controllers, system availability, branches, and connectors. The Controller List defines how the air loop will respond due to various inputs (control signals). The Availability Manager List refers to methods for controlling when a system is operational. This may be as simple as a schedule to define when the system is shutdown. The Branch List lists the branches that comprise the primary air system. Finally, the Connector List lists the connections between the branches. The branches and connections together define the primary air system topology.

The only numeric input is the design primary air flow rate. This item is input just before the *BranchList* name.

The next series of names refer to nodes for the various inlet and outlet points of the air loop. The air loop starts where the zone equipment ends. This is a single point consisting of the return air duct once all of the zone return air streams have been collected. While in reality, there is really only one point, for clarity within the simulation components and consistency with the other HVAC loop sections, this point in the systems is defined as two points: one that resides with the zone equipment simulation and one that is acted upon by the air loop simulation. Both node names must be entered into the input file, and both nodes must have unique names. Similarly, the end points of the air loop that also correspond to the beginning points of the zone equipment loop must also be defined. These consist of names referencing lists of up to three pairs of node names as shown below. Up to three air loop outlets are allowed to accommodate the simulation of three deck systems.

Field: Name

This field is a unique, user assigned name for a single instance of an *AirLoopHVAC* object. Any other object referencing this *AirLoopHVAC* will use this name.

Field: Controller List Name

This field is the name of a *ControllerList* object. A Controller List is simply a list of controllers giving both controller name and type. This Controller List specifies all the controllers that will act on this primary air loop. The order of the controllers in the list is significant: controllers are simulated sequentially in the order given in the Controller List.

Field: Availability Manager List Name

This field is the name of a AvailabilityManagerList object. A Availability Manager List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this primary air loop. That is, they determine when and if this air loop is on or off, overriding the control provided by the central fan on/off schedule.

Field: Design Supply Air Flow Rate

This is the system primary air design volumetric flow rate in cubic meters per second.

Field: Branch List Name

This field is the object name of a BranchList object (see BranchList and Branch). The BranchList named here specifies all the branches composing the primary air system. These branches, together with the Connectors listed in the ConnectorList, define the primary air system topology.

Field: Connector List Name

This field is the name of ConnectorList object. This ConnectorList object lists all the Connectors (by type and name) that are included in this primary air system. These Connectors, together with the Branches in the BranchList, define the topology of the primary air system.

Field: Supply Side Inlet Node Name

The name of the air entrance node of this primary air system. This is the inlet node for return air for this air system.

Field: Demand Side Outlet Node Name

The name of the air outlet node for the zone equipment group (ZoneHVAC:EquipmentConnections objects) attached to the primary air system. This should be the outlet node of a AirLoopHVAC:ZoneMixer in the AirLoopHVAC:ReturnPath for the zone equipment group attached to this primary air system.

Field: Demand Side Inlet Node Names

This field can be the name of a node which is the air inlet node for the zone equipment group (see ZoneHVAC:EquipmentConnections objects) attached to this primary air system. Or, this field can be the name of a node list containing one or more nodes (up to 3). These nodes should be the inlet nodes to the AirLoopHVAC:ZoneSplitter or AirLoopHVAC:SupplyPlenum in each of the AirLoopHVAC:SupplyPaths for the zone equipment groups attached to this primary air system. For single duct systems, there is only one node name in this list. For two and three duct systems, the order of the nodes in this list must correspond with the order of the nodes in the Supply Side Outlet Node Names list.

Field: Supply Side Outlet Node Names

This field can be the name of a node which is the air outlet node for each supply duct of this primary air system. Or, this field can be the name of a node list containing one or more nodes (up to 3). The list can contain the names of up to three nodes. For single duct systems, there is only one node name in this list. For two and three duct systems, the order of the nodes in this list must correspond with the order of the nodes in the Demand Side Inlet Node Names list.

An example of this statement in an IDF is:

```

AirLoopHVAC,
Main Dual Duct Air Loop,           ! Primary Air Loop Name
Dual Duct System 1 Controllers,    ! Controller List
Dual Duct System 1 Schedule List , ! System Availability Manager List

HVAC,Sum,Tot SimAir Iterations []
HVAC,Sum,Tot SimAirLoopComponents Calls []

```

Air Loop System Cycle On/Off Status

This field is the availability status of an AirLoopHVAC. This status flag is a result of the calculations made by the System Availability Manager(s) listed in a System Availability Manager List. When a single availability manager is used in a System Availability Manager List, this is also the availability status reported by the specific availability manager (Ref. System Availability Manager Outputs). When multiple availability managers are used in a System Availability Manager List, the loop availability status is determined by the rules associated with AirLoopHVACs (see rules described for Group – System Availability Managers). The control status outputs are represented using integers 0 through 3.. These integers represent *NoAction* (0), *ForceOff* (1), *CycleOn* (2), and *CycleOnZoneFansOnly* (3). Since the status output is averaged, the output result may not correspond to the values described here when report variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Report Variable) to view the availability status at each simulation timestep.

HVACManage Iterations

AirLoop-Zone Iterations

Max SimAir Iterations

Tot SimAir Iterations

Tot SimAirLoopComponents Calls

These variables are simply counters of how many iterations were executed. The count for any given HVAC time step will be the iterations executed before convergence was achieved, or the max allowed in which case the simulation throws a warning and proceeds to the next time step.

Outdoor Air Ventilation Outputs

This section provides more detailed information on the reporting available for outdoor air ventilation. Sixteen cooling and heating load variables and eight energy summary variables are available that report the impact of system outdoor air on zone loads, system demand and total energy use. The representative air system shown in the diagram below shows outdoor air (OA), return air (RA), supply air (SA) and mixed air (MA).

Figure 79. Example System for Ventilation Loads Report

The overall effect of outdoor air on the system shown above can be summarized by considering the mixing box. In this system, part or all of the return air is replaced by outdoor air. The presence of any heat recovery will already be taken into account and thus will automatically be accounted for by using the outdoor air inlet conditions to the mixing box (point OA in the diagram) rather than actual outdoor air conditions. Thus, the overall energy impact of outdoor air (ventilation) on a particular system can be evaluated by multiplying the outdoor air mass flow rate by the enthalpy difference between the outdoor air entering the mixing box (OA) and the return air entering the mixing box (RA') as shown in the following equation.

$$\dot{q}_{OA} = \dot{m}_{OA} (h_{OA} - h_{RA'}) = \dot{m}_{sys} (h_{MA} - h_{RA'})$$

Ventilation Flow Outputs

The fresh air flow into each zones are reported using the ventilation flow output variables. The total outdoor air flow in a primary air system is divided to each zone based on the fraction of flow each zone is supplied. There are six variables which deals with the mechanical ventilation flow reporting. Those six variables are:

Zone Mechanical Ventilation Mass Flow Rate [kg/s]

Reports the average outdoor air mass flow rate to any zone over the reporting interval.

Zone Mechanical Ventilation Mass [kg]

Reports the total outdoor air mass that has been supplied to any zone over the reporting interval.

Zone Mechanical Ventilation Volume Flow Rate Standard Density [m³/s]

Reports the average outdoor air volume flow rate to any zone over the reporting interval, calculated using a standard density for air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

Zone Mechanical Ventilation Volume Standard Density [m³]

Reports the total outdoor air volume that has been supplied to a zone over the reporting interval, calculated using a standard density for air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

Zone Mechanical Ventilation Volume Flow Rate Current Density [m³/s]

Reports the average outdoor air volume flow rate to any zone over the reporting interval, calculated using the current density for zone air.

Zone Mechanical Ventilation Volume Current Density [m³]

Reports the total outdoor air volume that has been supplied to a zone over the reporting interval, calculated using the current density for zone air.

Zone Mechanical Ventilation Air Change Rate [ach]

Reports the air changes per hour in the zone due to the outside fresh air supplied by mechanical ventilation system.

The example syntax below shows the basic ventilation flow variables reported on an hourly basis.

```
Output:Variable,*,Zone Mechanical Ventilation Mass Flow Rate,Hourly;
Output:Variable,*,Zone Mechanical Ventilation Mass,Hourly;
Output:Variable,*,Zone Mechanical Ventilation Volume Flow Rate Standard Density,Hourly;
Output:Variable,*,Zone Mechanical Ventilation Volume Standard Density,Hourly;
Output:Variable,*,Zone Mechanical Ventilation Volume Flow Rate Current Density,Hourly;
Output:Variable,*,Zone Mechanical Ventilation Volume Current Density,Hourly;
Output:Variable,*,Zone Mechanical Ventilation Ventilation Air Change Rate,Hourly;
```

Ventilation Load Reports

The impact of system outdoor air on a particular zone may be calculated by summing the mass flow weighted \dot{q}_{OA} over the supply air paths (both cooling and heating) serving the zone as follows:

$$\dot{q}_{OA,Zone1} = \sum_{n=1}^{AirPathNum} \dot{q}_{OA} \frac{\dot{m}_n}{\dot{m}_{sys}}$$

Four output variables each for cooling and heating report the impact of the ventilation air on the zone load in the absence of ventilation air system interactions. The ventilation load output variables are:

Zone Mechanical Ventilation Cooling Load Increase: OverHeating[J]**Zone Mechanical Ventilation Heating Load Increase: OverHeating[J]**

The cooling/heating load that would occur once ventilation air met the zone cooling/heating load and continued to overcool/overheat the zone. No system effects are accounted for.

Zone Mechanical Ventilation Cooling Load Decrease[J]**Zone Mechanical Ventilation Heating Load Decrease[J]**

The decrease in zone cooling/heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

Zone Mechanical Ventilation No Load Heat Removal[J]***Zone Mechanical Ventilation No Load Heat Addition[J]***

The addition or removal of heat to a zone with no load. The heat addition or removal is due to mechanical ventilation while the zone thermostat is in the deadband.

To summarize:

Cooling:**1. *Zone Mechanical Ventilation No Load Heat Removal [J]***

Cooling that would be provided directly to zone by ventilation air. Ventilation occurred with no zone load.

2. *Zone Mechanical Ventilation Cooling Load Increase [J]*

The increase in zone cooling load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

3. *Zone Mech Ventilation Cooling Load Increase: OverHeating [J]*

The cooling load that would occur once ventilation air met the zone heating load and continued to overheat the zone. No system effects are accounted for.

4. *Zone Mechanical Ventilation Cooling Load Decrease [J]*

The decrease in zone cooling load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

Heating:**1. *Zone Mechanical Ventilation No Load Heat Addition [J]***

Heating that would be provided directly to zone by ventilation air. Ventilation occurred with no zone load.

2. *Zone Mechanical Ventilation Heating Load Increase [J]*

The increase in zone heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

3. *Zone Mech Ventilation Heating Load Increase: OverCooling[J]*

The heating load that would occur once ventilation air met the zone cooling load and continued to overcool the zone. No system effects are accounted for.

4. *Zone Mechanical Ventilation Heating Load Decrease [J]*

The decrease in zone heating load that would occur as a result of ventilation air introduced directly into the zone. No system effects are accounted for.

The output variables are calculated by comparing the zone ventilation load with the zone cooling or heating load. ‘Ventilation cooling’ decreases the zone cooling load until the cooling load has been eliminated. The remaining ‘ventilation cooling’ is reported as ‘overcooling’. ‘Overheating’ is calculated in the same manner. The actual system operation, which determines whether or not an ‘overcooling’ or ‘overheating’ load actually results in increased energy consumption, is not considered in the calculation of these output variables.

The ventilation zone load output variables are shown in Table 24. The variables report the maximum potential “cost” or “benefit” of ventilation air introduced directly into the zone.

Table 24. Ventilation Load Output Variables

	No Zone Load	Zone Cooling Load	Zone Heating Load
Ventilation	Zone Mechanical Ventilation No Load	Zone Mechanical Ventilation Cooling	Zone Mechanical Ventilation Heating

Cooling	Heat Removal	Load Decrease	Load Increase
		Zone Mech Ventilation Heating Load Increase: OverCooling	
Ventilation Heating	Zone Mechanical Ventilation No Load Heat Addition	Zone Mechanical Ventilation Cooling Load Increase	Zone Mechanical Ventilation Heating Load Decrease
			Zone Mech Ventilation Cooling Load Increase: OverHeating

The example syntax below shows the basic ventilation load variables reported on a monthly basis.

```
Output:Variable,*,Zone Mechanical Ventilation Heating Load Increase,monthly;
Output:Variable,*,Zone Mechanical Ventilation Heating Load Decrease,monthly;
Output:Variable,*,Zone Mechanical Ventilation No Load Heat Addition,monthly;
Output:Variable,*,Zone Mechanical Ventilation Cooling Load Increase,monthly;
Output:Variable,*,Zone Mechanical Ventilation Cooling Load Decrease,monthly;
Output:Variable,*,Zone Mechanical Ventilation No Load Heat Removal,monthly;
```

Reporting on a timestep or hourly level would produce a detailed report with variables intermingled with the other output variables that might be requested in the input file.

Another method will more easily encapsulate the report:

```
OutputControl:Table:Style,
  HTML;           !- ColumnSeparator

Output:Table:Monthly,
  Ventilation Loads,      !- Name
  ,                      !- DigitsAfterDecimal
  Zone Mechanical Ventilation No Load Heat Removal,      SumOrAverage,
  Zone Mech Ventilation Cooling Load Increase: OverHeating, SumOrAverage,
  Zone Mechanical Ventilation Cooling Load Decrease,      SumOrAverage,
  Zone Mechanical Ventilation Cooling Load Increase,      SumOrAverage,
  Zone Mechanical Ventilation No Load Heat Addition,      SumOrAverage,
  Zone Mech Ventilation Heating Load Increase: OverCooling, SumOrAverage,
  Zone Mechanical Ventilation Heating Load Decrease,      SumOrAverage,
  Zone Mechanical Ventilation Heating Load Increase,      SumOrAverage;
```

This combination will report the ventilation loads on a monthly basis in a HTML style report that can be easily read in a web browser. Review the Output:Table:Monthly object for other methods of display or further options on this report item.

Systems Level Reporting

Most output variables are a single entity reporting. Meters are a combination of like variables – specifically for Energy Consumption. This section introduces a slightly different concept – where output variables described herein are a combination of several similar items – specifically targeted at HVAC/System level reporting. This reporting is coupled with an Air Loop (ref: AirLoopHVAC)

All items shown in this section are typical “output variables” and can be reported with the Output:Variable object.

Or, as is shown by example here, perhaps a more readable form is to generate them in Tabular Form with the “Output:Table:Monthly” object.

Figure 80. View of System Level Reporting

System Loads Outputs

In this category, the total system load is reported. Two aspects are reported here: Heating and Cooling. The following two variables report the heat energy that system components (including packaged equipment, fans, main coils, reheat coils, humidifiers, desiccant dehumidifiers, evaporative coolers and heat exchangers) add or remove from the air loop. Each variable within these grouping will

Air Loop Total Heating Energy

Heat Addition to the Air Loop (Sum of all components) in Joules

Air Loop Total Cooling Energy

Heat Removal from the Air Loop (Sum of all components) in Joules

In 'Output:Table:Monthly' format shown below.

```

OutputControl:Table:Style ,
  HTML;           !- ColumnSeparator

Output:Table:Monthly,
  System Loads,      !- Name
  ,                  !- DigitsAfterDecimal
  Air Loop Total Heating Energy, SumOrAverage,
  Air Loop Total Cooling Energy, SumOrAverage;
  
```

System Energy Use Outputs

System Energy Use consists of six output variables that report the total energy (in Joules) and water consumption (in m³) for all system components and including packaged equipment, fans, main coils, reheat coils, humidifiers, desiccant dehumidifiers, and evaporative coolers. The output variables shown below show hot and cold water, steam, electric and gas energy. Hot and cold water energy includes all 'district cooling' and 'district heating' energy.

Air Loop Hot Water Consumption

Hot Water Consumption for the system (Joules).

Air Loop Steam Consumption

Steam Consumption for the system (Joules).

Air Loop Chilled Water Consumption

Chilled Water Consumption for the system (Joules).

Air Loop Electric Consumption

Electric Consumption for the system (Joules).

Air Loop Gas Consumption

Gas (Natural Gas and Propane) Consumption for the system (Joules).

Air Loop Water Consumption

Water Consumption for the system (humidifiers and evaporative coolers) (m³).

The Standard reports file includes these variables reporting in the Tabular report form as "Air Loop System Energy and Water Use".

```
OutputControl:Table:Style,
  HTML;           !- ColumnSeparator

Output:Table:Monthly,
  Air Loop System Energy and Water Use,      !- Name
  ,                                         !- DigitsAfterDecimal
  Air Loop Hot Water Consumption , SumOrAverage,
  Air Loop Steam Consumption , SumOrAverage,
  Air Loop Chilled Water Consumption, SumOrAverage,
  Air Loop Electric Consumption, SumOrAverage,
  Air Loop Gas Consumption, SumOrAverage,
  Air Loop Water Consumption, SumOrAverage;
```

System Component Loads Outputs

Reporting System Component Loads shows the energy transferred to or extracted from the air loop by system component type. Fans, Cooling Coils, Heating Coils, Heat exchangers, humidifiers, evaporative coolers, and desiccant dehumidifiers show heat transfer rates in Joules. The components may be located in outdoor air systems bundled with packaged equipment or specified as stand-alone components. The reporting accounts for both main branch and reheat coils.

The Standard reports file includes these variables reporting in the Tabular report form as "Air Loop System Component Loads".

```
OutputControl:Table:Style,
  HTML;           !- ColumnSeparator

Output:Table:Monthly,
  Air Loop System Component Loads,      !- Name
  ,                                         !- DigitsAfterDecimal
  Air Loop Fan Heating Energy, SumOrAverage,
  Air Loop Total Cooling Coil Energy, SumOrAverage,
  Air Loop Total Heating Coil Energy, SumOrAverage,
  Air Loop Total Heat Exchanger Heating Energy, SumOrAverage,
  Air Loop Total Heat Exchanger Cooling Energy, SumOrAverage,
  Air Loop Total Humidifier Heating Energy, SumOrAverage,
```

Air Loop Total Evap Cooler Cooling Energy, SumOrAverage,
Air Loop Total Desiccant Dehumidifier Cooling Energy, SumOrAverage;

Air Loop Fan Heating Energy

Energy added to the air loop by Fans (Joules)

Air Loop Total Cooling Coil Energy

Energy removed from air loop by Cooling Coils (Joules)

Air Loop Total Heating Coil Energy

Energy added to air loop by Heating Coils (Joules)

Air Loop Total Heat Exchanger Heating Energy

Energy added to air loop by air-to-air heat recovery heat exchangers (Joules)

Air Loop Total Heat Exchanger Cooling Energy

Energy removed from air loop by air-to-air heat recovery heat exchangers (Joules)

Air Loop Total Humidifier Heating Energy

Energy added to air loop by humidifiers (Joules)

Air Loop Total Evap Cooler Cooling Energy

Energy removed from air loop by evaporative coolers (Joules)

Air Loop Total Desiccant Dehumidifier Cooling Energy

Energy removed from air loop by desiccant dehumidifiers (Joules)

Air Loop Total Solar Collector Heating Energy

Energy added to air loop by solar collectors (Joules)

Air Loop Total Solar Collector Cooling Energy

Energy removed from air loop by solar collectors (Joules)

Air Loop Total User Defined Terminal Heating Energy

Energy added to air loop by user defined air terminal units (Joules)

Air Loop Total User Defined Terminal Cooling Energy

Energy removed from air loop by user defined air terminal units (Joules)

System Component Energy Use Outputs

Reporting System Component Energy Use consists of eleven output variables that report the total energy consumption (in Joules) of system components by energy type and coil type. Electric energy consumption is reported for fans, heating and cooling coils in packaged (DX) systems, electric resistance heating coils, humidifiers, evaporative coolers and desiccant dehumidifiers.

Air Loop Fan Electric Consumption

Electric consumption for fans. (Joules)

Air Loop Heating Coil Hot Water Consumption

Consumption for heating coil hot water (both purchased and plant supplied) (Joules)

Air Loop Cooling Coil Chilled Water Consumption

Consumption for cooling coil chilled water (both purchased and plant supplied) (Joules)

Air Loop DX Heating Coil Electric Consumption

Compressor plus condenser fan electricity use. (Joules)

Air Loop DX Cooling Coil Electric Consumption

Compressor plus condenser fan electricity use. (Joules)

Air Loop Heating Coil Electric Consumption

Electricity consumption for the heating coil. (Joules)

Air Loop Heating Coil Gas Consumption

Gas (Propane and Natural Gas) consumption for the heating coil. (Joules)

Air Loop Heating Coil Steam Consumption

Steam consumption for the heating coil (steam coils). (Joules)

Air Loop Humidifier Electric Consumption

Electricity consumption for the humidifiers. (Joules)

Air Loop Evap Cooler Electric Consumption

Electricity consumption for the evaporative coolers. (Joules)

Air Loop Desiccant Dehumidifier Electric Consumption

Electricity consumption for the desiccant dehumidifiers. (Joules)

The Standard reports file includes these variables reporting in the Tabular report form as "Air Loop System Component Energy Use".

```
OutputControl:Table:Style,
  HTML;                                !- ColumnSeparator

Output:Table:Monthly,
  Air Loop System Component Energy Use,      !- Name
  ,                                         !- DigitsAfterDecimal
  Air Loop Fan Electric Consumption, SumOrAverage,
  Air Loop Heating Coil Hot Water Consumption, SumOrAverage,

  Air Loop DX Cooling Coil Electric Consumption, SumOrAverage,
  Air Loop Heating Coil Electric Consumption, SumOrAverage,
  Air Loop Heating Coil Gas Consumption, SumOrAverage,
  Air Loop Heating Coil Steam Consumption, SumOrAverage,
  Air Loop Humidifier Electric Consumption, SumOrAverage,
  Air Loop Evap Cooler Electric Consumption, SumOrAverage,
  Air Loop Desiccant Dehumidifier Electric Consumption, SumOrAverage;
```

Overall Air Loop Syntax

A map for Air Loop input syntax is shown in the following diagram.

Figure 81. Air Loop Input Syntax Map

AirLoopHVAC:ControllerList

The syntax for the AirLoopHVAC:ControllerList definition is shown below. As with other lists in EnergyPlus input, the object title and identifying name are followed by type-name pairs. In this case, the types are controller types. The order in which controllers appear on this list also define the priority as described below. The identifying name refers back to the name recorded in the AirLoopHVAC statement.

Field: Name

The user designated unique name of an instance of a Controller List. Any object referencing this Controller List will do so using this name.

Field Set (Object Type, Controller Name) up to 8

After the identifying name, input for the controller list consists of up to 8 pairs of data items: a controller type and a controller name. The first controller listed has the highest priority, the second the second highest priority, and so forth.

Field: Controller <x> Object Type

The type of controller. This should be a key word defining a class of controllers such as Controller:WaterCoil.

Field: Controller <x> Name

The name of a controller object (such as a Controller:WaterCoil) defined elsewhere in the input file.

An example of this statement in an IDF is:

```
AirLoopHVAC:ControllerList,
  Dual Duct System 1 Controllers,
  Controller:WaterCoil, Main Cooling Coil Controller,
  Controller:WaterCoil, Main Heating Coil Controller;
```

AvailabilityManagerAssignmentList

The AvailabilityManagerAssignmentList defines the applicable managers used for an AirLoopHVAC or PlantLoop. The priority of availability managers is based on a set of rules and are specific to the type of loop. The output from each Availability Manager is an availability status flag. This flag can have the values *NoAction*, *ForceOff*, *CycleOn*, or *CycleOnZoneFansOnly* (used only for air loops). The availability status flags for the Availability Managers referenced by an air or plant loop are used to set the availability status flag for each loop. For the air loops, *ForceOff* takes precedence: if any of the loop's availability managers are showing status *ForceOff*, the loop status will be *ForceOff*. Next in precedence is *CycleOnZoneFansOnly*, followed by *CycleOn*, and *NoAction*. For the plant loops, there is no precedence among the Availability Manager status flag values. Instead, the first availability manager giving a status flag value other than *NoAction* sets the status for the loop. The Availability Managers are executed in Availability Manager List order.

Special rules also apply for which managers may be listed in a Availability Manager list. The Hybrid Ventilation Control Manager (object: AvailabilityManager:HybridVentilation) is a special type of manager and is never specified in a Availability Manager List (it is used stand-alone for a specific air loop). All other types of availability managers may be listed in the Availability Manager List used for AirLoopHVACs. For Plant Loops, the Night Cycle and Night Ventilation managers (objects: AvailabilityManager:NightCycle and AvailabilityManager:NightVentilation) are not allowed in the Availability Manager List.

Field: Name

The name of the AvailabilityManagerAssignmentList object. This is referenced by AirLoopHVAC and PlantLoop objects.

Field Set (Availability Manager Object Type, Name)

Managers are listed by pairs of data items: *Availability Manager Object Type* and *Availability Manager Name*. The managers are simulated down the list and calculate a control status for use by the AirLoopHVAC or PlantLoop. The priority of each manager used for a specific loop is based on the rules described above. Availability managers are not currently used for condenser loops. The availability managers, along with the AirLoopHVAC and PlantLoop object, report the control status calculated each simulation timestep. These output variables can be used to prioritize the managers according to the required control strategy. Six managers are accomodated in the list by default, however, this IDD specification is extensible. Additional pairs may be added by directly editing the IDD.

Field: Availability Manager <x> Object Type

The key word defining the type of manager, e.g. AvailabilityManager:NightCycle.

Field: Availability Manager<x> Name

The name of a AvailabilityManager object defined elsewhere in the input file.

An example of this statement in an IDF is:

```

AvailabilityManagerAssignmentList,
  Collector Loop Availability Manager List, !- Name
  AvailabilityManager:HighTemperatureTurnOff, !- System Availability Manager Type 1
  High Temperature Turn Off Availability Manager, !- System Availability Manager Name 1
  AvailabilityManager:LowTemperatureTurnOn, !- System Availability Manager Type 2
  Low Temperature Turn On Availability Manager, !- System Availability Manager Name 2
  AvailabilityManager:DifferentialThermostat, !- System Availability Manager Type 3
  Differential Thermostat Availability Manager; !- System Availability Manager Name 3

```

AirLoopHVAC:OutdoorAirSystem

The Outside Air System (object AirLoopHVAC:OutdoorAirSystem) is a subsystem of an AirLoopHVAC. It handles the mixed air portion of the primary air system: the system relief air, the outside air inlet, and any components and controllers associated with the system relief air and outside air streams. From the perspective of the primary air loop the Outside Air System is treated as a single component. As a subsystem, it can contain one or more components and controllers.

The input for the Outside Air System consists of a system name, a controller list name, an equipment list name, and an availability manager list name. The controller list simply lists, by type and unique name, all the controllers in the subsystem. The controllers will be simulated in list order. The equipment list lists all the components in the subsystem, by type and name. The equipment is simulated in list order. Finally, the availability manager list gives the type and name of the availability managers used by the subsystem.

The equipment inlet/outlet must be sequential with no loops - the simulation can only handle a straight-through air path, both on the primary air side and on the secondary air side, if any. Heat exchanger secondary air inlets need to be independent of the primary air stream – usually relief air is used.

Field: Name

The unique, user assigned name for a single instance of an Outside Air System. Any other object referencing this Outside Air System will use this name.

Field: Name: Controller List Name

This field is the name of a AirLoopHVAC:ControllerList object. A AirLoopHVAC:ControllerList is simply a list of controllers giving both controller name and type. This Controller List specifies all the controllers that will act on this outside air system. The order of the controllers in the list is significant: controllers are simulated sequentially in the order given in the Controller List. Typically the Controller List would contain a Controller:OutdoorAir. If there are chilled water or hot water coils in the outdoor air system, each such coil will need a Controller:WaterCoil.

Field: Outdoor Air Equipment List Name

This field is the name of an AirLoopHVAC:OutdoorAirSystem:EquipmentList object. An AirLoopHVAC:OutdoorAirSystem:EquipmentList is simply a list of components giving both component name and type. This Outdoor Air Equipment List specifies all the components that will be simulated in this outside air system. The order of the components in the list is significant: components are simulated sequentially in the order given in the Outdoor Air Equipment List. Typically the equipment list would contain at least an OutdoorAir:Mixer. If there is more than one component, the components must be listed in order from the outside air to the OutdoorAir:Mixer (the OutdoorAir:Mixer is last).

Field: Availability Manager List Name

This field is the name of a AvailabilityManagerAssignmentList object. An Availability Manager List is a list of Availability Managers giving both Availability Manager Object Type and Name. **Use of this input is optional.** This field may be omitted; it is not currently used by the program.

An IDF example, including the AirLoopHVAC, and the controller and equipment lists.

```

```

Outdoor Air System Outputs

The impact of using outside air/mechanical ventilation is described in the section: Outdoor Air Ventilation Outputs.

AirLoopHVAC:OutdoorAirSystem:EquipmentList

Used to specify the components in the outdoor air system. The components will be simulated in the order in which they occur in the list.

Field: Name

The user designated unique name of an instance of an Air Loop Equipment List. Any object referencing this Air Loop Equipment List will do so using this name.

Field Set (Component Object Type,, Component Name) up to 8

After the identifying name, the list consists of up to 8 pairs of data items:

Field: Component <x> Object Type

This field specifies the keyword for the type of component used.

Field: Component <x> Name

This field is the unique name of the component specified in the previous field. This named object must appear in the IDF.

An example from an IDF:

```
AirLoopHVAC:OutdoorAirSystem:EquipmentList,
  OA Sys 1 Equipment,
  HeatExchanger:AirToAir:FlatPlate,OA Heat Recovery 1,
  OutdoorAir:Mixer, OA Mixing Box 1;
```

OutdoorAir:Node

The OutdoorAir:Node object declares an HVAC system node for outdoor air conditions. The program automatically sets the air conditions at these nodes to correspond to the ambient environmental conditions at the beginning of every timestep. The outdoor air node is typically used as the inlet air node to an HVAC component such as the OutdoorAir:Mixer object. Multiple OutdoorAir:Node objects can be used in an input file, however, duplicate node names are not allowed.

The *Height Above Ground* field is used to adjust the weather file air conditions, e.g., outdoor dry-bulb and wet-bulb air temperatures, for atmospheric variation with height. This variation can become a significant factor when modeling tall buildings. See the Engineering Reference section on Atmospheric Variation for a description of the algorithm for variation of atmospheric properties with height. A blank entry or a value less than zero for this field indicates that the height will be ignored and the weather file conditions will be used.

OutdoorAir:Node and **OutdoorAir:NodeList** both set a node to outdoor air conditions. **OutdoorAir:Node** modifies the weather file conditions if a height has been specified. **OutdoorAir:NodeList** does not have a height input and always uses the weather file conditions without modification. The same node name may not be used with both of these objects.

Field: Name

The unique name for this outdoor air node.

Field: Height Above Ground

The height [m] of the node above ground level. A value greater than zero allows the weather file conditions, e.g., outdoor dry-bulb and wet-bulb air temperatures, to be adjusted according to atmospheric variation with height.

A blank entry or value less than zero indicates that the height will be ignored and the weather file conditions will be used.

An example IDF:

```
OutdoorAir:Node,
  OA Node 1;  !- Name

OutdoorAir:Node,
  Floor 10 Outdoor air Inlet Node,  !- Name
  30.0;  !- Height Above Ground {m}
```

OutdoorAir:Node outputs:

The ambient dry-bulb air temperature and flow rate at the outdoor air node can be monitored using the system node output variables:

HVAC,Average,System Node Temp[C]
HVAC,Average,System Node MassFlowRate[kg/s]

e.g.

```
Output:Variable,
Floor 10 Outdoor air Inlet Node,
System Node Temp,
Hourly;
```

OutdoorAir:NodeList

The program needs to know which HVAC system nodes are inlets for outdoor air. Knowing this, the program can set the conditions at these nodes to the outdoor conditions at the start of each major timestep. The **OutdoorAir:NodeList** provides the means for specifying which nodes are outdoor air nodes.

The input is flexible: there may be one or more **OutdoorAir:NodeList** in each input file. Each list contains up to 25 names. The names can be the name of a unique HVAC system node, or the name of a **Node List** which will contain the actual node names. Duplicate node names are ignored.

OutdoorAir:Node and **OutdoorAir:NodeList** both set a node to outdoor air conditions. **OutdoorAir:Node** modifies the weather file conditions if a height has been specified. **OutdoorAir:NodeList** does not have a height input and always uses the weather file conditions without modification. The same node name may not be used with both of these objects.

Field: Node or NodeList name

The name of an HVAC system node or of a **NodeList** object. There can be up to 25 names.

An example IDF:

```
OutdoorAir:NodeList,
  OutsideAirInletNodes;

NodeList,OutsideAirInletNodes,
  Outdoor air Inlet Node;
```

OutdoorAir:Mixer

The **OutdoorAir:Mixer** is the most common component used in an outdoor air system. The outdoor air mixer has 2 inlet air streams: the system return air and the outdoor air. It has 2 outlet air streams: the system relief air and the mixed air. This is a passive component. It takes the inlet mass flows and conditions plus the relief air mass flow and calculates the mixed air flow rate and conditions (as well as the relief air conditions). The inlet and relief mass flow must be set outside the component – most commonly by an outdoor air controller. The **OutdoorAir:Mixer** can also be used in compound components such as a fan coil unit.

Input for this object is very simple: a unique name plus the node names of the 2 inlet nodes and the 2 outlet nodes.

Field: Name

A unique user assigned name for a particular outdoor air mixer component. Any reference to this component by another object will use this name.

Field: Mixed Air Node Name

The name of the HVAC system node which is the outlet for the mixed air stream.

Field: Outdoor Air Stream Node Name

The name of the HVAC system node which is the inlet for the outdoor air stream.

Field: Relief Air Stream Node Name

The name of the HVAC system node which is the outlet for the system relief air.

Field: Return Air Stream Node Name

The name of the HVAC system node which is the inlet for the return air stream.

An IDF example:

```
OutdoorAir:Mixer,
Zone1WindACOAMixer,           ! name
Zone1WindACOAMixerOutletNode, ! mixer outlet node
Zone1WindACOAINode,           ! mixer OA node
Zone1WindACExhNode,           ! mixer relief node
Zone1WindACAAirInletNode;     ! mixer inlet node
```

Group – Airflow Network

Overview

The Airflow Network model provides the ability to simulate multizone airflows driven by wind and also by a forced air distribution system. The model can also simulate the heat and moisture gains or losses from the air distribution system itself (e.g., ductwork). When modeling an air distribution system, the current version of the Airflow Network model is restricted to a single forced air system (i.e., AirLoopHVAC object) with a constant volume supply air fan (Fan:ConstantVolume or Fan:OnOff). The capabilities of the model are to:

- Simulate zone pressures due to envelope leakage and forced air distribution during HVAC system fan operation
- Simulate node pressures in a forced air distribution system during HVAC system fan operation
- Calculate multizone airflows due to forced air, wind, and surface leakage, including adjacent zones and outdoors, during HVAC system fan operation
- Simulate distribution system airflows, including supply and return air leaks, during HVAC system fan operation
- Simulate air distribution system node temperatures and humidity ratios during HVAC system fan operation
- Calculate duct conduction losses during HVAC system fan operation
- Calculate vapor diffusion losses of ducts during HVAC system fan operation
- Calculate sensible and latent loads on the surrounding zones due to supply and return air leaks in the air distribution system during HVAC system fan operation
- Simulate zone pressures due to envelope leakage driven by wind when the HVAC system fan is off or if no air distribution system is specified
- Calculate multizone airflows due to wind and surface leakage, including adjacent zones and outdoors when the HVAC system fan is off or if no air distribution system is specified
- Allow zone exhaust fans to be included as part of the airflow network
- For airflow networks with a forced air distribution system, calculate zone sensible and latent loads for two different supply air fan operation modes as required: cycling fan, cycling compressor (CyclingFanAndCompressor) and continuous fan, cycling compressor (ContinuousFanWithCyclingCompressor)

Summary of Objects

Before describing the Airflow Network input objects in detail, we list all of the objects and then give a short description of what the objects do.

The Airflow Network input objects are:

AirflowNetwork:SimulationControl
AirflowNetwork:Multizone:Zone
AirflowNetwork:Multizone:Surface

AirflowNetwork:MultiZone:Component:SimpleOpening
AirflowNetwork:MultiZone:Component:DetailedOpening
AirflowNetwork:MultiZone:Component:HorizontalOpening
AirflowNetwork:MultiZone:Surface:Crack

- **AirflowNetwork:SimulationControl** defines basic run parameters for the air flow calculations and specifies whether wind pressure coefficients are input by the user or, for rectangular buildings, calculated by the program.
- The **AirflowNetwork:Multizone:Zone** object specifies the ventilation control that applies to all of the openable exterior and interior windows and doors in the corresponding thermal zone. Surface-level ventilation control can be used to override the zone-level ventilation control if required (see **AirflowNetwork: Multizone:Surface** object below).
- **AirflowNetwork:Multizone:Surface** object indicates whether a heat transfer surface (wall, window, etc.) has a crack or opening and references an **AirflowNetwork:MultiZone:Surface:Crack**,
AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea,
AirflowNetwork:MultiZone:Component:SimpleOpening,
AirflowNetwork:MultiZone:Component:DetailedOpening,
AirflowNetwork:MultiZone:Component:HorizontalOpening or **AirflowNetwork:MultiZone:Component:ZoneExhaustFan** object that gives the air flow characteristics of that crack, opening, or zone exhaust fan. The **AirflowNetwork:Multizone:Surface** object can also be used to specify individual ventilation control for openable exterior and interior windows and doors.
- **AirflowNetwork:MultiZone:ReferenceCrackConditions** is used to normalize crack information that is based on measurements of crack air flow.
- **AirflowNetwork:Distribution:Node** represents air distribution system nodes for the **AirflowNetwork** model. A set of an **AirLoopHVAC** and **ZoneHVAC:EquipmentList** nodes is a subset of the **AirflowNetwork:Distribution:Nodes**.
- **AirflowNetwork:Distribution:Component** objects consist of **Leak**, **LeakageRatio**, **Duct**, **ConstantPressureDrop**, **ConstantVolumeFan**, **Coil**, and **TerminalUnit**. The components provide a relationship between pressure and airflow. The **Leak** and **Leakage** components can be used to simulate supply and/or return leaks in an air distribution system. The **Duct** and **ConstantPressureDrop components** can be used to deliver forced air into conditioned spaces. The components **ConstantVolumeFan**, **Coil**, and **TerminalUnit** reference normal EnergyPlus objects. The **Airflow Network** model gets information from these objects to perform an airflow network simulation.
- **AirflowNetwork:Distribution:Linkage** object represents a connection between two node objects and an **AirflowNetwork** component. The node objects can be an

AirflowNetwork:Distribution:Node, AirflowNetwork:MultiZone:ExternalNode or
AirflowNetwork:Multizone:Zone.

If you input wind pressure coefficients, **AirflowNetwork:Multizone:Surface** also has an associated **AirflowNetwork:MultiZone:ExternalNode**, that, via the **AirflowNetwork:Multizone:WindPressureCoefficientArray** and **AirflowNetwork:MultiZone:WindPressureCoefficientValues** objects, gives the wind pressure distribution vs. wind direction for that node and, implicitly, for the cracks and openings in the exterior surfaces associated with that node.

Figure 82 shows the relationships among AirflowNetwork:Multizone objects and between AirflowNetwork:Multizone objects and regular EnergyPlus objects. In this figure an arrow from object A to object B means A references B, i.e., one of the inputs in A is the name of object B. For example, one input for AirflowNetwork: Multizone:Surface is the name of a heat transfer surface, and another is the name of a crack or opening object. The arrow between AirflowNetwork:Multizone:Surface and AirflowNetwork:MultiZone:ExternalNode is shown dashed to indicate that this reference is not used when wind pressure coefficients are calculated by the program rather than being input by the user.

Figure 82 also shows the relationships among AirflowNetwork:Distribution objects and between AirflowNetwork:Distribution objects and regular EnergyPlus objects. The AirflowNetwork:Distribution:Linkage objects link two nodes from AirflowNetwork:Distribution:Node and/or AirflowNetwork:Multizone:Zone objects with a component defined in the object AirflowNetwork:Distribution:Component. The solid arrows show a reference from object A to object B. The dashed arrows indicate the components which can be used in a linkage object. The red arrows pointing to the Zone object indicate the components that interact with the zone air. For example, the temperature in a zone where a supply leak terminates is used to calculate duct leakage energy loss. The temperature in a zone where a duct component is located is also used to calculate duct conduction loss.

Figure 82. Relationships among AirflowNetwork objects (right-hand side) and between AirflowNetwork objects and regular EnergyPlus objects. An arrow from object A to object B means that A references B.

Much of the information needed for the air flow calculation is automatically extracted from the building description for thermal modeling. This includes things like the volume and neutral height of the zones, and the orientation and location of the building surfaces that contain cracks or openings through which air flows. From all of this information the program creates a “pressure-flow network” that is solved each timestep using iterative solution methods to obtain the unknown pressures and air flows.

Figure 83 shows a plan view of a very simple air flow network that you can construct using the above AirflowNetwork objects. There are three thermal zones, Zone-1, Zone-2 and Zone-3. There are openable exterior windows—Window-1, Window-2 and Window-3—and openable interior doors—Door-12 and Door-23. Two External Nodes are indicated. ExternalNode-1 is associated with the façade that contains Window-1 and Window-2. ExternalNode-2 is associated with the façade containing Window-3.

One possible air flow pattern is shown in this figure. The actual air flow pattern in a particular timestep, and the size of the flows, depends on many factors, such as (1) What is the wind pressure distribution seen by the exterior windows? (2) Are the exterior windows open or closed, and if open, how far are they open? (3) Are the interior doors open or closed? (4) What are the air temperature differences between zones and between zones and the outdoor air (which affect buoyancy flows)?

Figure 83. Plan view of a simple air flow network showing a possible air flow pattern in which all of the windows and doors are open.

Figure 83 shows a possible air flow pattern in which all of the windows and doors are open. Associated with the external nodes are wind pressure coefficient distributions as a function of wind direction that are input using two `AirflowNetwork:Multizone:Wind Pressure Coefficient` objects. The nature of the air flows through the windows and doors is specified using `AirflowNetwork:MultiZone:Component:DetailedOpening` and `AirflowNetwork:MultiZone:Component:SimpleOpening` objects. The Airflow Network model calculates the flows each system timestep depending on various factors, including wind direction and speed, size and vertical position of openings, outdoor air temperature, and zone air temperatures.

What the Airflow Network Model Can and Cannot Do

Here is a list of some of the things that the Airflow Network calculation can and cannot model.

Can Do

- 1) Air flow through cracks in exterior or interzone surfaces.
- 2) Air flow through cracks around windows and doors when closed.
- 3) Natural ventilation (i.e., air flow through open or partially open exterior windows and doors).
- 4) Zone level control of natural ventilation (all windows/doors in a zone that are defined with a component opening object have identical controls).
- 5) Individual surface control of natural ventilation for a subsurface (window, door, or glassdoor).
- 6) Modulation of natural ventilation to prevent large zone air temperature swings.
- 7) Interzone air flow (i.e., air flow through open interzone windows and doors, and through cracks in interzone surfaces).
- 8) Dependence of air flow on buoyancy effects and wind pressure.
- 9) Dependence of wind pressure on wind speed, wind direction and surface orientation.
- 10) Supply and return air leaks in an air distribution system.
- 11) Account for the effect of supply-air and/or return-air leakage on zone pressure when a forced air distribution system is present and is operating.
- 12) When duct leakage is modeled and the HVAC system is on, interzone airflow or infiltration/exfiltration can occur due to changes in zone pressure.
- 13) Bi-directional flow through large openings. See discussion below under AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:Multizone:Component:HorizontalOpening, and AirflowNetwork:Multizone:Component:SimpleOpening.
- 14) Calculate air flows and pressures in ducts or other components of a forced air distribution system.
- 15) Calculate zone loads when the supply air fan cycles on and off during a system timestep using the CyclingFanAndCompressor fan operation mode (Fan:OnOff).
- 16) Determine the impact of zone exhaust fans on air flows, pressures, air temperatures/humidity levels and energy consumption.

Cannot Do or Restricted

- 1) The model is restricted to using a constant volume fan (Fan:ConstantVolume and Fan:OnOff) and cannot model variable volume fan equipment.
- 2) Air circulation and/or air temperature stratification within a thermal zone. For example, you should not try to divide a high space, such as an atrium, into subzones separated by artificial horizontal surfaces that have cracks or openings with the expectation that AirflowNetwork will give you a realistic temperature in each subzone and/or a realistic air flow between subzones.

- 3) The model is restricted to eleven types of coils that can be in the air distribution system (Coil:Cooling:DX:SingleSpeed, Coil:Heating:Gas, Coil:Heating:Electric, Coil:Heating:DX:SingleSpeed, Coil:Cooling:Water, Coil:Heating:Water, Coil:Cooling:Water:DetailedGeometry, Coil:Cooling:DX:TwoStageWithHumidityControlMode, Coil:Cooling:DX:MultiSpeed, Coil:Heating:DX:MultiSpeed, and Coil:Heating:Desuperheater).
- 4) The model is restricted to a single type of air distribution equipment terminal units (AirTerminal:SingleDuct:ConstantVolume:Reheat).
- 5) Pollutant transport cannot currently be modeled.
- 6) Supply and return leaks are not allowed in an AirLoopHVAC. They can only be modeled in the Zone Equipment portion of the air loop (i.e., return leaks may be modeled between the zone return node and the zone mixer inlet or the zone mixer outlet and the zone equipment loop outlet; and supply leaks may be modeled between the zone equipment loop inlet and the AirLoopHVAC:ZoneSplitter inlet node or the AirLoopHVAC:ZoneSplitter outlet node and the zone supply node).
- 7) An air distribution system must be located inside the building (i.e., the ducts must pass through zones within the building).
- 8) Zone exhaust fans must be defined in ZoneHVAC:EquipmentConnections objects.

The input specifications consist of five main sections: **AirflowNetwork:SimulationControl object**, **AirflowNetwork multizone data objects**, **AirflowNetwork distribution node objects**, **AirflowNetwork distribution component objects**, and **AirflowNetwork distribution linkage objects**. Each of these object types is described in detail below.

AirflowNetwork:SimulationControl

The basic run parameters for this model are defined in this unique object which has the following input specifications:

Field: Name

This is a unique character string associated with this instance of the AirflowNetwork:SimulationControl object. At this time, only one AirflowNetwork:SimulationControl object can be specified in an input data file (idf).

Field: AirflowNetwork Control

The following selections are available to control the Airflow Network simulation:

MultizoneWithDistribution: Multizone air flow calculations are performed during all simulation timesteps, including the impacts of the air distribution system when a HVAC system fan is operating. Any **ZoneInfiltration:***, **ZoneVentilation:***, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are not simulated.

MultizoneWithoutDistribution: Multizone air flow calculations are performed during all simulation timesteps, but the air distribution system portion of the network is not modeled even if it is specified in the input data file. Any **ZoneInfiltration:***, **ZoneVentilation:***, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are not simulated.

MultizoneWithDistributionOnlyDuringFanOperation: Multizone air flow calculations, including the impacts of the air distribution system, are only performed when the HVAC system fan is operating. Any **ZoneInfiltration:***, **ZoneVentilation:***, **ZoneMixing** and **ZoneCrossMixing** objects specified in the input data file are used when the HVAC system fan is OFF (if none are specified, then no air flow calculations are performed when the fan is OFF).

NoMultizoneOrDistribution: No multizone air flow calculations (with or without the air distribution system portion of the network) are performed during the simulation. Any **ZoneInfiltration:***, **ZoneVentilation:***, **ZoneMixing** and **ZoneCrossMixing** objects specified

in the input data file are simulated (if none are specified, then no air flow calculations are performed). Note: Having an input data file with no AirflowNetwork:SimulationControl objects gives the same impact – no multizone air flow calculations. However, this choice is provided as a convenience to the user to easily disable the multizone air flow calculations for an input data file that already contains AirflowNetwork objects.

Note: A ZoneInfiltration:*** object indicates any one of ZoneInfiltration:DesignFlowRate, ZoneInfiltration:EffectiveLeakageArea, and ZoneInfiltration:FlowCoefficient objects. A object of ZoneVentilation:*** indicates any one of ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects.

Field: Wind Pressure Coefficient Type

Determines whether the wind pressure coefficients are input by the user or calculated. The choices are **Input** or **SurfaceAverageCalculation**, with the default being SurfaceAverageCalculation.

If INPUT, you must enter an AirflowNetwork:MultiZone:WindPressureCoefficientArray object, one or more AirflowNetwork:MultiZone:ExternalNode objects, and one or more AirflowNetwork:MultiZone:WindPressureCoefficientValues objects.

The second choice, SurfaceAverageCalculation, should only be used for **rectangular** buildings. In this case surface-average wind pressure coefficients vs. wind direction are calculated by the program for the four vertical facades and the roof based on user entries for "Building Type," "Azimuth Angle of Long Axis of Building," and "Ratio of Building Width Along Short Axis to Width Along Long Axis" (see description of these fields below). With this choice you do **not** have to enter any of the following objects: AirflowNetwork:MultiZone: Wind Pressure Coefficient Array, AirflowNetwork:MultiZone:ExternalNode and AirflowNetwork:MultiZone:WindPressureCoefficientValues.

Field: AirflowNetwork Wind Pressure Coefficient Array Name

This is the name of the AirflowNetwork:MultiZone:WindPressureCoefficientArray object that contains wind directions corresponding to the wind pressure coefficients given in the AirflowNetwork:MultiZone:WindPressureCoefficientValues objects.

A value need be entered only if Wind Pressure Coefficient Type = INPUT (see description of previous field).

Field: Height Selection for Local Wind Speed Calculation

Determines whether the local wind speed is calculated based on either given external node heights or surface opening heights. The choices are **ExternalNode** or **OpeningHeight**, with the default being OpeningHeight. The local outdoor wind speed calculation procedure is given in the section of "Local Wind Speed Calculation" in the Engineering Reference. The calculation procedure requires the height input.

If **ExternalNode**, the heights given in the AirflowNetwork:MultiZone:ExternalNode objects are used to calculate local wind speeds. Used only if Wind Pressure Coefficient Type = INPUT (see description of previous field).

If **OpeningHeight**, the number of the AirflowNetwork:MultiZone:ExternalNode objects has to be equal to the number of external surfaces defined in the AirflowNetwork:MultiZone:Surface objects. The centroids in the z direction of the AirflowNetwork:MultiZone:Surface objects are the heights used in the local wind speed calculation. The input is required if Wind Pressure Coefficient Type = INPUT (see description of previous field).

If Wind Pressure Coefficient Type = **SurfaceAverageCalculation**, a value in this field is not required and a blank may be entered. The default choice is used internally to generate the AirflowNetwork:MultiZone:ExternalNode objects

Field: Building Type

Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The choices for Building Type are LowRise and HighRise, with the default being LowRise.

LowRise corresponds to a rectangular building whose height is less than three times the width of the footprint (w_{short} in Figure 84) and is less than three times the length of the footprint (w_{long} in the same figure).

HighRise corresponds to a rectangular building whose height is more than three times the width of the footprint (w_{short} in Figure 84) or is more than three times the length of the footprint (w_{long} in the same figure).

Field: Maximum Number of Iterations

The maximum number of iterations allowed in finding an AirflowNetwork solution. If the number of iterations at each simulation timestep is above the maximum number of iterations defined by this field, the program could not find the solution and a Severe error is issued and the program is aborted. The default value is 500.

Field: Initialization Type

Designates which method is used for AirflowNetwork initialization. The choices for Initialization Type are LinearInitializationMethod and ZeroNodePressures, with the default being ZeroNodePressures.

Field: Relative Airflow Convergence Tolerance

The solution is assumed to have converged when $\left| \sum \dot{m}_i \right| / \left| \sum \dot{m}_i \right|$ is less than the value specified for this input field. This convergence criteria is equivalent to the ratio of the absolute value of the sum of all network airflows ($\left| \sum \dot{m}_i \right|$) to the sum of network airflow magnitudes ($\sum \left| \dot{m}_i \right|$). The default value is 1.0×10^{-4} .

Field: Absolute Airflow Convergence Tolerance

The solution is assumed to have converged when the summation of the absolute value of all network airflows ($\left| \sum \dot{m}_i \right|$) is less than the value specified for this input field. The default value is 1.0×10^{-6} .

Field: Convergence Acceleration Limit

If the ratio of successive pressure corrections is less than this limit, use Steffensen acceleration algorithm (Ref. AirflowNetwork Model in the EnergyPlus Engineering Reference). The range for this field is -1 to 1, with the default value being -0.5.

Field: Azimuth Angle of Long Axis of Building

Gives the orientation of a rectangular building for calculating wind pressure coefficients. This is the smaller of the angles, measured clockwise, between North and the long axis of the building (see Figure 84). Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The range for this input is 0 to 180, with the default value being 0.

Field: Ratio of Building Width Along Short Axis to Width Along Long Axis

This is the aspect ratio of a rectangular footprint. It is given by the width of the footprint along its short axis divided by the width along the long axis (see Figure 84). If the footprint is

square, the value of this field is 1.0. Used only if Wind Pressure Coefficient Type = SurfaceAverageCalculation. The range for this input is > 0 to 1, with the default value being 1.

Figure 84. Footprint of a rectangular building showing variables used by the program to calculate surface-average wind pressure coefficients. The angle α is the “Azimuth Angle of Long Axis of Building.”

w_{short}/w_{long} is the “Ratio of Building Width Along Short Axis to Width Along Long Axis.”

AirflowNetwork:Multizone data objects are used to calculate multizone airflows. This section describes the input requirements for the following objects:

- AirflowNetwork:MultiZone:Zone

AirflowNetwork:Multizone data objects are used to calculate multizone airflows. This section describes the input requirements for the following objects:

- AirflowNetwork:MultiZone:Zone
- AirflowNetwork:MultiZone:Surface
- AirflowNetwork:MultiZone:Surface:Crack
- AirflowNetwork:MultiZone:ReferenceCrackConditions
- AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea
- AirflowNetwork:MultiZone:Component:DetailedOpening
- AirflowNetwork:MultiZone:Component:SimpleOpening
- AirflowNetwork:MultiZone:Component:HorizontalOpening

- AirflowNetwork:MultiZone:Component:ZoneExhaustFan
- AirflowNetwork:MultiZone:ExternalNode
- AirflowNetwork:MultiZone:WindPressureCoefficientArray
- AirflowNetwork:MultiZone:WindPressureCoefficientValues

A detailed description for each of these objects is provided below.

AirflowNetwork:Multizone:Zone

This object allows control of natural ventilation through exterior and interior openings in a zone, where “opening” is defined as an openable window or door. (Note that only window, door or glass door subsurfaces in a zone that are specified using AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:HorizontalOpening or AirflowNetwork:Multizone:Component:SimpleOpening and have an associated AirflowNetwork:Multizone:Surface object are considered to be openings). The control will be applied in the same way to all of the openings in the zone.

This object is required to perform Airflow Network calculations. Note that ventilation control for all openings is provided at the zone level as default and individual ventilation control of a surface opening can be used to override the zone-level control (see the AirflowNetwork:Multizone:Surface object description below).

Field: Zone Name

The name of the EnergyPlus thermal zone corresponding to the AirflowNetwork zone.

Field: Ventilation Control Mode

Specifies the type of zone-level natural ventilation control.

Let T_{out} equal the outdoor air temperature, T_{zone} equal the previous timestep's zone air temperature, T_{set} equal the Vent Temperature Schedule value, H_{zone} equal the specific enthalpy of zone air from the previous timestep, and H_{out} equal the specific enthalpy of outdoor air. Then the four allowed choices for Ventilation Control Mode are:

NoVent: All of the zone's openable windows and doors are closed at all times independent of indoor or outdoor conditions. The Venting Availability Schedule is ignored in this case. This is the default value for this field.

Temperature: All of the zone's openable windows and doors are opened if $T_{zone} > T_{out}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule (see below) allows venting.

Enthalpy: All of the zone's openable windows and doors are opened if $H_{zone} > H_{out}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule allows venting.

Constant: Whenever this object's Venting Availability Schedule allows venting, all of the zone's openable windows and doors are open, independent of indoor or outdoor conditions. Note that “Constant” here means that the size of each opening is fixed while venting; the air flow through each opening can, of course, vary from timestep to timestep.

ASHRAE55Adaptive: All of the zone's operable windows and doors are opened if the operative temperature is greater than the comfort temperature (central line) calculated from the ASHRAE Standard 55-2010 adaptive comfort model and Venting Availability Schedule allows venting.

CEN15251Adaptive: All of the zone's operable windows and doors are opened if the operative temperature is greater than the comfort temperature (central line) calculated from the CEN15251 adaptive comfort model and Venting Availability Schedule allows venting.

Field: Ventilation Control Zone Temperature Setpoint Schedule Name

The name of a schedule of zone air temperature set points that controls the opening of windows and doors in the thermal zone to provide natural ventilation. This setpoint is the temperature above which all the openable windows and doors in the zone will be opened if the conditions described in the previous field Ventilation Control Mode are met.

The Ventilation Control Zone Temperature Setpoint Schedule Name applies only to windows and doors in the zone that are specified using AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:HorizontalOpening or AirflowNetwork:MultiZone:Component:SimpleOpening and have an associated AirflowNetwork:MultiZone:Surface object.

(The discussion under the field Window/Door Opening Factor in the AirflowNetwork:MultiZone:Surface object describes how the actual opening area of a window or door in a particular timestep is determined.)

Modulation of Openings

The following five fields can be used to modulate the window/door openings when Ventilation Control Mode = Temperature or Enthalpy. These fields determine a factor between 0 and 1 that multiplies the opening factor of each window and door in the zone according to the control action shown in Figure 85 for Ventilation Control Mode = Temperature and in Figure 86 for Ventilation Control Mode = Enthalpy. Modulation of the openings can reduce the large temperature swings that can occur if the windows/doors are open too far when they are venting, especially when there is a large inside-outside temperature difference.

The modulation takes the following form when Ventilation Control Mode = Temperature:

$T_{zone} - T_{out} \leq [Lower\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor]$ → Multiplication factor = 1.0

$[Lower\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor] < T_{zone} - T_{out} < [Upper\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor]$ → Multiplication factor varies linearly from 1.0 to [Limit Value on Multiplier for Modulating Venting Open Factor]

$T_{zone} - T_{out} \geq [Upper\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor]$ → Multiplication factor = [Limit Value on Multiplier for Modulating Venting Open Factor]

One way of “tuning” the following modulation control parameters is to perform a sensitivity analysis for winter and/or summer design days to determine what combination of values causes the biggest reduction in zone air temperature fluctuations due to venting.

Note that the default values for the following fields are such that, if none of the fields are specified, the default values are assigned.

Field: Minimum Venting Open Factor

See Figure 85 or Figure 86. This field applies only if Ventilation Control Mode = Temperature or Enthalpy. This value may be from zero to 1.0, with the default being 0.0.

Field: Indoor and Outdoor Temperature Difference Lower Limit For Maximum Venting Open Factor

See Figure 85. This field applies only if Ventilation Control Mode = Temperature. This value may be from zero to less than 100°C, with the default being 0°C. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Temperature Difference Upper Limit for Minimum Venting Open Factor

See Figure 85. This field applies only if Ventilation Control Mode = Temperature. This value must be greater than 0°C, with the default being 100°C. The value for this field must be greater than the value specified for the previous field..

Field: Indoor and Outdoor Enthalpy Difference Lower Limit For Maximum Venting Open Factor

See Figure 86. This field applies only if Ventilation Control Mode = Enthalpy. This value may be from zero to less than 300,000 J/kg, with the default being 0 J/kg. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Enthalpy Difference Upper Limit for Minimum Venting Open Factor

See Figure 86. This field applies only if Ventilation Control Mode = Enthalpy. This value must be greater than zero, with the default being 300,000 J/kg. The value for this field must be greater than the value specified for the previous field.

Field: Venting Availability Schedule Name

The name of a schedule that specifies when venting is available. A zero or negative schedule value means venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by Ventilation Control Mode and Vent Temperature Schedule Name) are satisfied. This schedule name should not be confused with Vent Temperature Schedule Name.

If a Venting Availability Schedule Name is not specified, it is assumed that venting is always available.

Using Venting Availability Schedule allows you to turn off venting at certain times of the day (at night, for example), of the week (on weekends, for example), or of the year (during the winter, for example).

If used with Ventilation Control Mode = Constant, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero.

If Ventilation Control Mode = NoVent, this schedule has no effect.

Figure 85. Modulation of venting area according to inside-outside temperature difference.

Figure 86. Modulation of venting area according to inside-outside enthalpy difference.

Note: In order to establish an airflow network, each `AirflowNetwork:Multizone:Zone` object must have at least two surfaces defined with `AirflowNetwork:Multizone:Surface` objects, so that air can flow from one zone into other zones (or to outdoors) through the network (air mass flow conserved). In addition, for all `AirflowNetwork:Multizone:Surface` objects facing the same Zone (ref. `BuildingSurface:Detailed`), at least

two different environments must be defined for the other side of these surfaces (e.g., an external node and an adjacent zone, two adjacent zones, or two external nodes).

AirflowNetwork:Multizone:Surface

The AirflowNetwork:Multizone:Surface object specifies the properties of a surface “linkage” through which air flows. This linkage is always associated with a heat transfer surface (wall, roof, floor, or a ceiling) or subsurface (door, glass door, or window) with both faces exposed to air. The linkage specifies two connected nodes: two zone nodes defined in AirflowNetwork:Multizone:Zone objects based on inside and outside face environment for an interior surface, or a zone node defined in an AirflowNetwork:Multizone:Zone object based on inside face environment and an external node defined in an AirflowNetwork:MultiZone:ExternalNode object for an exterior surface. The associated leakage component for this surface can be a crack (or surface effective leakage area) in an exterior or interior heat transfer surface or subsurface, or an exterior or interior window, door or glass door (heat transfer subsurface) that can be opened to allow air flow. The allowed surface air leakage components are:

- AirflowNetwork:MultiZone:Surface:Crack
- AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea
- AirflowNetwork:MultiZone:Component:DetailedOpening
- AirflowNetwork:MultiZone:Component:HorizontalOpening
- AirflowNetwork:MultiZone:Component:SimpleOpening
- AirflowNetwork:MultiZone:Component:ZoneExhaustFan

The two “opening” components are used to modulate openness based on required conditions.

The AirflowNetwork:Multizone:Surface object allows a heat transfer surface or subsurface to have one crack (or one surface effective leakage area object), or a subsurface (i.e., window, door or glass door) to have one opening (detailed or simple).

An interior heat transfer surface (BuildingSurface:Detailed) whose surface name is used as the input for the Outside Boundary Condition Object field represents a floor without ground contact and is not allowed as an AirflowNetwork:Multizone:Surface. A heat transfer surface defined in the BuildingSurface:Detailed:ExteriorNaturalVentedCavity is also not allowed.

Field: Surface Name

This is the name of the corresponding surface (wall, roof, ceiling, floor, window, door or glass door).

Information on this surface is used by the program as follows:

- (1) For a linkage associated with an exterior heat transfer surface: air flow through this linkage is between the outside environment and the thermal zone to which the surface belongs.
- (2) For a linkage associated with an interior (i.e., interzone) heat transfer surface: air flow through this linkage is between the thermal zones separated by the surface (i.e., the thermal zone associated with the inside face environment and the thermal zone associated with the outside face environment).
- (3) This heat transfer surface determines the height of the linkage, which is used in calculating buoyancy-related flow through the linkage.

Note: It is possible to define an interzone surface twice in EnergyPlus, once in each of the zones that the surface separates. Previously this was a requirement of EnergyPlus (prior to version 2.0), but now it is optional and the user also has the option of only defining the surface once (EnergyPlus defines the second surface automatically within the program). For each interzone surface, use only one (of possible two) interzone surface names in the AirflowNetwork:Multizone:Surface object for "Surface Name." **Do not** enter two AirflowNetwork:Multizone:Surface objects corresponding to the two possible interzone names. This would cause the air flow through the surface to be counted twice.

Field: Leakage Component Name

The name of the AirflowNetwork:MultiZone:Surface:Crack, AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea, AirflowNetwork:MultiZone:Component:SimpleOpening, AirflowNetwork:MultiZone:Component:HorizontalOpening, AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:MultiZone:Component:ZoneExhaustFan object associated with this air flow linkage.

If the name of an opening component (i.e. AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:HorizontalOpening, or AirflowNetwork:MultiZone:Component:SimpleOpening is given here, then the Surface Name in the previous field must be that of a window, door or glass door heat transfer subsurface. Otherwise an error message will be reported.

If the name of an AirflowNetwork:MultiZone:Surface:Crack object or AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea object is given here, the program will position the crack at the average height of the associated heat transfer surface or subsurface. The user can define multiple heat transfer surfaces (e.g., split a wall into several surfaces) to be more precise in establishing the crack location. Similarly, the user can define multiple heat transfer surfaces if a wall, for example, has multiple cracks or openings that need to be defined individually.

If the name of an AirflowNetwork:MultiZone:Component:ZoneExhaustFan is given here, then the Surface Name in the previous field must be that of an exterior heat transfer surface. The zone name defined in the Zone Name field for this heat transfer surface must be the same zone name defined in the ZoneHVAC:EquipmentConnections object (which references a ZoneHVAC:EquipmentList containing the name of the corresponding zone exhaust fan). Otherwise an error message will be reported. When this zone exhaust fan is operating for a simulation timestep, all surface-level controls described below are ignored for that timestep.

Field: External Node Name

The name of the associated AirflowNetwork:MultiZone:ExternalNode object, which determines the wind pressure coefficients for the heat transfer surface. Used only if Surface Name is for an exterior surface.

If Wind Pressure Coefficient Type = SurfaceAverageCalculation in the AirflowNetwork:SimulationControl object, this field is not used and a blank may be entered. If the surface is an interior (i.e., interzone) surface, leave this field blank.

Field: Window/Door Opening Factor, or Crack Factor

If this linkage is associated with an AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:MultiZone:Component:SimpleOpening object (which means it is an openable window or door), then this field is called “Window/Door Opening Factor” and represents the value of the Opening Factor that is in effect when the Vent Temperature Schedule (defined in the AirflowNetwork:Multizone:Zone object) indicates that this window or door is open.

The AirflowNetwork model uses a combination of factors to determine the actual opening area for a window or door when it is venting. For example, consider a window that is 1.5m high and 2.0m wide (excluding frame). Assume that the AirflowNetwork:MultiZone:Component:DetailedOpening for this window has Type of Large Vertical Opening = 1 (non-pivoting window), Height Factor = 0.5 and Width Factor = 0.8. Then when the window is fully open, the opening area = height of opening (0.5x1.5) times width of opening (0.8x2.0) = $0.75 \times 1.6 = 1.2 \text{ m}^2$. If the Window/Door Opening Factor is 0.75, then the opening area = $0.75 \times 1.2 = 0.9 \text{ m}^2$.

If, in addition, the window is in a thermal zone for which opening modulation has been specified (ref: AirflowNetwork:Multizone:Zone) and the multiplication factor due to modulation is 0.3 in a particular timestep, then the actual opening factor at timestep = $0.3 \times 0.75 = 0.225$ and the actual opening area at timestep = $0.3 \times 0.9 = 0.27 \text{ m}^2$.

If this linkage is associated with an AirflowNetwork:MultiZone:Surface:Crack object, the following crack air flow equation is used.

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n$$

Where

Q = air mass flow (kg/s)

C_Q = air mass flow coefficient (kg/s @ 1 Pa)

C_T = reference condition temperature correction factor (dimensionless). See AirflowNetwork:MultiZone:Surface:Crack object.

ΔP = pressure difference across crack (Pa)

n = air flow exponent (dimensionless)

The following fields control venting. They are used only when Name of Associated Heat Transfer Surface is that of an openable exterior or interior window, door or glass door. They only apply to openings, and do not apply to surface cracks, effective leakage area or zone exhaust fans. If none of these fields is specified, or if Ventilation Control Mode = ZoneLevel, venting is controlled by the AirflowNetwork:Multizone:Zone object for the thermal zone containing the window or door (ref: AirflowNetwork:Multizone:Zone Data).

Field: Ventilation Control Mode

Specifies the type of surface-level natural ventilation control.

Let T_{out} equal the outdoor air temperature, T_{zone} equal the previous timestep's zone air temperature, T_{set} equal the Vent Temperature Schedule value, H_{zone} equal the specific

enthalpy of zone air from the previous timestep, and H_{out} equal the specific enthalpy of outdoor air. Then the four allowed choices for Ventilation Control Mode are:

NoVent: The openable window or door associated with this surface is closed at all times independent of indoor or outdoor conditions. The Venting Availability Schedule is ignored in this case.

Temperature: The openable window or door associated with this surface is opened if $T_{zone} > T_{out}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule (see below) allows venting.

Enthalpy: The openable window or door associated with this surface is opened if $H_{zone} > H_{out}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule allows venting.

Constant: Whenever this object's Venting Availability Schedule allows venting, the openable window or door associated with this surface is open, independent of indoor or outdoor conditions. Note that "Constant" here means that the size of this opening is fixed while venting; the air flow through this opening can, of course, vary from timestep to timestep.

ASHRAE55Adaptive: The openable window or door associated with this surface is opened if the operative temperature is greater than the comfort temperature (central line) calculated from the ASHRAE Standard 55-2010 adaptive comfort model and Venting Availability Schedule allows venting.

CEN15251Adaptive: The openable window or door associated with this surface is opened if the operative temperature is greater than the comfort temperature (central line) calculated from the CEN15251 adaptive comfort model and Venting Availability Schedule allows venting.

ZoneLevel: Venting of the window or door is not controlled individually, but is controlled instead at the zone level. This means that the venting is determined by the AirflowNetwork:Multizone:Zone object for the thermal zone containing the window or door (ref: AirflowNetwork:Multizone:Zone object). This is the default value for this field.

AdjacentTemperature: This choice is used for an interior surface only. The openable interior window or door associated with this surface is opened if $T_{zone} > T_{adjacent\ zone}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule (see below) allows venting, where $T_{adjacent\ zone}$ is the adjacent zone temperature.

AdjacentEnthalpy: This choice is also used for an interior surface only. The interior openable window or door associated with this surface is opened if $H_{zone} > H_{adjacent\ zone}$ and $T_{zone} > T_{set}$ and Venting Availability Schedule allows venting, where $H_{adjacent\ zone}$ is the adjacent zone specific enthalpy.

Field: Ventilation Control Zone Temperature Setpoint Schedule Name

The name of a schedule of zone air temperature set points that controls the opening of a window or door associated with this surface to provide natural ventilation. This setpoint is the temperature above which this openable window or door will be opened if the conditions described in the previous field Ventilation Control Mode are met.

The Ventilation Control Zone Temperature Setpoint Schedule applies only to a window or door attached to this surface that is specified using AirflowNetwork:MultiZone:Component:DetailedOpening or AirflowNetwork:MultiZone:Component:SimpleOpening.

(The discussion under the field Window/Door Opening Factor in this object describes how the actual opening area of a window or door in a particular timestep is determined.)

Modulation of Openings

The following five fields can be used to modulate this window/door opening when Ventilation Control Mode = Temperature or Enthalpy. These fields determine a factor between 0 and 1 that multiplies the opening factor of this window or door according to the control action shown in Figure 85 for Ventilation Control Mode = Temperature and in Figure 86 for Ventilation Control Mode = Enthalpy. Modulation of this opening can reduce the large temperature swings that can occur if the window/door is open too far when it is venting, especially when there is a large inside-outside temperature difference.

The modulation takes the following form when Ventilation Control Mode = Temperature:

$T_{zone} - T_{out} \leq [Lower\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor]$ → Multiplication factor = 1.0

$[Lower\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor] < T_{zone} - T_{out} < [Upper\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor]$ → Multiplication factor varies linearly from 1.0 to [Limit Value on Multiplier for Modulating Venting Open Factor]

$T_{zone} - T_{out} \geq [Upper\ Value\ on\ Inside/Outside\ Temperature\ Difference\ for\ Modulating\ the\ Venting\ Open\ Factor]$ → Multiplication factor = [Limit Value on Multiplier for Modulating Venting Open Factor]

One way of “tuning” the following modulation control parameters is to perform a sensitivity analysis for winter and/or summer design days to determine what combination of values causes the biggest reduction in zone air temperature fluctuations due to venting.

Note that the default values for the following fields are such that, if none of the fields are specified, modulation will not occur.

Field: Minimum Venting Open Factor

See Figure 85 or Figure 86. This field applies only if Ventilation Control Mode = Temperature or Enthalpy. This value may be from zero to 1.0, with the default being 0.0.

Field: Indoor and Outdoor Temperature Difference Lower Limit For Maximum Venting Open Factor

See Figure 85. This field applies only if Ventilation Control Mode = Temperature. This value may be from zero to less than 100°C, with the default being 0°C. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Temperature Difference Upper Limit for Minimum Venting Open Factor

See Figure 85. This field applies only if Ventilation Control Mode = Temperature. This value must be greater than 0°C, with the default being 100°C. The value for this field must be greater than the value specified for the previous field.

Field: Indoor and Outdoor Enthalpy Difference Lower Limit For Maximum Venting Open Factor

See Figure 86. This field applies only if Ventilation Control Mode = Enthalpy. This value may be from zero to less than 300,000 J/kg, with the default being 0 J/kg. The value for this field must be less than the value specified for the following field.

Field: Indoor and Outdoor Enthalpy Difference Upper Limit for Minimum Venting Open Factor

See Figure 86. This field applies only if Ventilation Control Mode = Enthalpy. This value must be greater than zero, with the default being 300,000 J/kg. The value for this field must be greater than the value specified for the previous field.

Field: Venting Availability Schedule Name

The name of a schedule that specifies when venting is available. A zero or negative schedule value means venting is not allowed. A value greater than zero means venting can occur if other venting control conditions (specified by Ventilation Control Mode and Vent Temperature Schedule Name) are satisfied. This schedule name should not be confused with Vent Temperature Schedule Name.

If a Venting Availability Schedule Name is not specified, it is assumed that venting is always available.

Using Venting Availability Schedule allows you to turn off venting at certain times of the day (at night, for example), week (on weekends, for example), or year (during the winter, for example).

If used with Ventilation Control Mode = Constant, the ventilation rate is constant only when this schedule allows venting; otherwise the ventilation rate is set to zero.

If Ventilation Control Mode = NoVent, this schedule has no effect.

Note: In order to establish an airflow network, each AirflowNetwork:Multizone:Zone object must have at least two surfaces defined with AirflowNetwork:Multizone:Surface objects, so that air can flow from one zone into other zones (or to outdoors) through the network (air mass flow conserved). In addition, for all AirflowNetwork:Multizone:Surface objects facing the same Zone Name (ref. BuildingSurface:Detailed), at least two different environments must be defined for the other side of these surfaces (e.g., an external node and an adjacent zone, two adjacent zones, or two external nodes).

AirflowNetwork:MultiZone:ReferenceCrackConditions

This object specifies the reference conditions for temperature, humidity, and pressure which correspond to the AirflowNetwork:MultiZone:Surface:Crack object.

Field: Name

The name of this Reference Crack Conditions object. This name is referenced by an AirflowNetwork:MultiZone:Surface:Crack object.

Field: Reference Temperature

The reference temperature in °C under which the Surface Crack Data were obtained. The default value is 20°C.

Field: Reference Barometric Pressure

The reference barometric pressure in Pa under which the Surface Crack Data were obtained. The default value is 101325 Pa.

Field: Reference Humidity Ratio

The reference humidity ratio in kg/kg under which the Surface Crack Data were obtained. The default value is 0 kg/kg.

An IDF example is provided below:

```

AirflowNetwork:MultiZone:ReferenceCrackConditions,
ReferenceCrackConditions,      !- Name of Reference Crack Conditions
20.0,                          !- Reference Temperature for Crack Data {C}
101325,                        !- Reference Barometric Pressure for Crack Data {Pa}
0.0;                           !- Reference Humidity Ratio for Crack Data {kg/kg}

```

AirflowNetwork:MultiZone:Surface:Crack

This object specifies the properties of air flow through a crack and the associated measurement conditions. The following power law form is used that gives air flow through the crack as a function of the pressure difference across the crack:

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n$$

Where

Q = air mass flow (kg/s)

C_Q = air mass flow coefficient (kg/s-Paⁿ @ 1 Pa)

C_T = reference condition temperature correction factor (dimensionless)

ΔP = pressure difference across crack (Pa)

n = air flow exponent (dimensionless)

$$C_T = \left[\frac{\rho_o}{\rho} \right]^{n-1} \left[\frac{v_o}{v} \right]^{2n-1}$$

where

ρ = Air density at the specific air temperature and humidity ratio conditions [kg/m³]

v = Air kinetic viscosity at the specific air temperature condition [m²/s]

ρ_o = Air density at the reference air conditions provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [kg/m³]

v_o = Air kinetic viscosity at the reference air temperature provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [m²/s]

Note: The correction factor shown above is use for this particular component as specified.

Field: Name

This is a name for this AirflowNetwork:MultiZone:Surface:Crack object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Air Mass Flow Coefficient at Reference Conditions

The value of the air mass flow coefficient, C_Q , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero.

Field: Air Mass Flow Exponent

The value of the exponent, n , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.

Field: Reference Crack Conditions

The name of the AirflowNetwork:MultiZone:ReferenceCrackConditions object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one AirflowNetwork:MultiZone:ReferenceCrackConditions object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one AirflowNetwork:MultiZone:ReferenceCrackConditions objects are defined in the input data file, then the default conditions for the AirflowNetwork:Multizone: Reference Crack Conditions object will be used.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Surface:Crack,
  CR-1,           !- Name of Surface Crack Component
  0.01,          !- Air Mass Flow Coefficient at Reference Conditions {kg/s}
  0.667,         !- Air Mass Flow Exponent {dimensionless}
  ReferenceCrackConditions; !- Reference Crack Conditions
```

AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea

The effective leakage area (ELA) object is used to define surface air leakage. It has

five fields. The relationship between pressure and airflow may be expressed as:

$$\dot{m} = ELA * C_d \sqrt{2\rho} * (\Delta P_r)^{0.5-n} (\Delta P)^n$$

where

- \dot{m} = Air mass flow rate [kg/s]
- ELA = Effective leakage area [m^2]
- ρ = Air density [kg/m^3]
- ΔP_r = Reference pressure difference [Pa]
- ΔP = Pressure difference across this component [Pa]
- C_d = Discharge coefficient [dimensionless]
- n = Air mass flow exponent [dimensionless]

Field: Name

This is a name for this AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Effective Leakage Area

This numeric field is used to input the effective leakage area in square meters. The effective leakage area is used to characterize openings for infiltration calculations (ASHRAE Handbook of Fundamentals, 1997, pp 25.18). This value must be greater than zero.

Field: Discharge Coefficient

This numeric field is used to input the discharge coefficient. This value must be greater than zero, with a default value of 1.0.

Field: Reference Pressure Difference

This numeric field is used to input the reference pressure difference [Pa]. This value must be greater than zero, with a default value of 4.0 Pa.

Field: Air Mass Flow Exponent

This numeric field is used to input the pressure difference exponent. The valid range of the exponent is from 0.5 to 1.0, with a default value of 0.65.

Note: There are two common sets of reference conditions: $C_d = 1.0$ and $\Delta P = 4$ Pa, or $C_d = 0.6$ and $\Delta P = 10$ Pa

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Surface:EffectiveLeakageArea,
  SurfaceELR,           !- Name of surface effective leakage area component
  0.07,                 !- Effective leakage area {dimensionless}
  1.00,                 !- Discharge coefficient {dimensionless}
  4.0,                  !- Reference pressure difference {Pa}
  0.65;                !- Air mass flow exponent {dimensionless}
```

AirflowNetwork:MultiZone:Component:DetailedOpening

This object specifies the properties of air flow through windows and doors (window, door and glass door heat transfer subsurfaces) when they are closed or open. The fields are similar to those for AirflowNetwork:Multizone:SurfaceCrack object when the window or door is closed, but additional fields are required to describe the air flow characteristics when the window or

door is open. These additional fields include opening type, opening dimensions, degree of opening, and opening schedule.

The AirflowNetwork model assumes that open windows or doors are vertical or close to vertical; for this reason they are called “Large Vertical Openings.” Such openings can have air flow moving simultaneously in two different directions depending on stack effects and wind conditions (for example, flow from inside to outside at the top of a window and from outside to inside at the bottom). AirflowNetwork models such two-directional flow, but only for vertical openings.

It is assumed that the air flow through a window opening is unaffected by the presence of a shading device such as a shade or blind on the window. Also, the calculation of conductive heat transfer and solar gain through a window or door assumes that the window or door is closed.

The AirflowNetwork model does not have a model for bi-directional flow through large horizontal openings. For this reason, **AirflowNetwork:MultiZone:Component:DetailedOpening** should not be used for horizontal openings. The best modeling technique in this case is to put an AirflowNetwork:MultiZone:Surface:Crack object in a horizontal surface and use a large air mass flow coefficient. Crack flow is assumed to be uni-directional in any given timestep (but can reverse flow direction from timestep to timestep).

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

Field: Name

The name of this AirflowNetwork:MultiZone:Component:DetailedOpening object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Air Mass Flow Coefficient When Opening is Closed

Crack flow is assumed when the window or door is closed. The units for this air mass flow coefficient ($C_{Q, \text{unit length}}$) are different from the units for C_Q (kg/s at 1 Pa pressure difference) defined in an AirflowNetwork:MultiZone:Surface:Crack object. There is no default but the entered value must be greater than zero. The program will automatically generate four cracks around the perimeter of the window or door--one along the bottom, one along the top, and one on each side. The temperature correction factor used in the AirflowNetwork:MultiZone:Surface:Crack object is not used for this component to calculate air mass flow rate.

Field: Air Mass Flow Exponent When Opening Is Closed

Crack flow is assumed when the window or door is closed. In this case, the value of this field is the exponent, n , in the crack air flow equation. The valid range for this exponent is 0.5 to 1.0, with the default value being 0.65.

Field: Type of Rectangular Large Vertical Opening (LVO)

This alpha field specifies the type of rectangular window or door. (Open windows or doors are also called Large Vertical Openings (LVOs). The choices for the opening type are **NonPivoted** (LVO Type 1) and **HorizontallyPivoted** (LVO Type 2) with the default being **NonPivoted**. The NonPivoted type represents a regular window or door. The HorizontallyPivoted type represents a window with a horizontal axis ((i.e., a horizontally-pivoting window) and cannot be used for a door.

Field: Extra Crack Length or Height of Pivoting Axis

Specifies window or door characteristics that depend on the LVO type.

For LVO Type 1 (rectangular non-pivoted windows and doors) this field is the extra crack length in meters due to multiple openable parts, if present. “Extra” here means in addition to the length, calculated by the program, of the cracks on the top, bottom and sides of the window/door.

For LVO Type 2 (rectangular horizontally-pivoted windows) this field gives the height of the pivoting axis measured from the bottom of the glazed part of the window (m).

Field: Number of Sets of Opening Factor Data

This is the number of the following sets of data for opening factor, discharge coefficient, width factor, height factor, and start height factor. From two to four of these sets must be defined. The first set should be for Opening Factor = 0.0 and the last set should be for Opening Factor = 1.0. For example, if only two sets are defined, the first set should be for Opening Factor = 0.0 and the second set should be for Opening Factor = 1.0, as shown below in the IDF example below.

An “opening factor” refers to the amount that a window or door is opened. The program linearly interpolates each timestep between the values of discharge coefficient, width factor, etc., in these sets using the opening factor for the window or door for the timestep. (See discussion under the field Window/Door Opening Factor in the AirflowNetwork:Multizone:Zone object for a description of how the AirflowNetwork model determines the time-step value of the opening factor.)

Field Group: Opening Factor, Discharge Coefficient, Width Factor, Height Factor, Start Height Factor

Each field is described for as many groups as required in the previous field (number of sets of opening factor data). As the final field has specific requirements, this field (n) will be described.

Field: Opening Factor 11

The first opening factor of a window or door. This value must be 0.0. The default value is also 0.0.

For LVO Type 1 (rectangular non-pivoted window or door), the Opening Factor corresponds to the fraction of window or door that is opened.

For LVO Type 2 (rectangular horizontally-pivoted windows), the Opening Factor is determined by the window opening angle. For example, an opening angle of 45° corresponds to an Opening Factor of 0.50 since the maximum opening angle is 90°.

Field: Discharge Coefficient for Opening Factor 1

The discharge coefficient of the window or door for Opening Factor 1. The range is greater than 0.0 to less than or equal to 1.0. The default value is 0.001. The Discharge Coefficient indicates the fractional effectiveness for air flow through a window or door at that Opening Factor.

Note: In the following, “window width” and “window height” are glazing dimensions; they do not include the frame, if present.

Field: Width Factor for Opening Factor 1

The Width Factor of the rectangular window or door for Opening Factor 1. The Width Factor is the opening width divided by the window or door width (see Figure 87). The range is 0.0 to 1.0. The default value is 0.0. Note that the width factor applies to rectangular windows or doors where the width is assumed constant along the entire height of the opening.

Field: Height Factor for Opening Factor 1

The Height Factor of the rectangular window or door for Opening Factor 1. The Height Factor is the opening height divided by the window or door height (see Figure 87). The range is 0.0 to 1.0. The default value is 0.0. Note that the height factor applies to rectangular windows or doors where the height is assumed constant along the entire width of the opening.

Field: Start Height Factor for Opening Factor 1

The Start Height Factor of the window or door for Opening Factor 1. The Start Height Factor is the Start Height divided by the window or door height (see Figure 87). The range is 0.0 to 1.0. The default is 0. Start Height is the distance between the bottom of the window or door and the bottom of the window or door opening. The sum of the Height Factor and the Start Height Factor must be less than 1.0 in order to have the opening within the window or door dimensions.

Figure 87. Window (or door) showing geometrical factors associated with an opening through which air flows.

Field: Opening Factor <n>

When Number of Sets of Opening Factor Data = n, the value of Opening Factor n must be set to 1.0.

Field: Discharge Coefficient for Opening Factor <n>

The discharge coefficient of the window or door for Opening Factor n. The range is greater than 0.0 to less than or equal to 1.0. The default value is 1.0.

Field: Width Factor for Opening Factor <n>

The Width Factor of the rectangular window or door for Opening Factor n. The Width Factor is the opening width divided by the window or door width (see Figure 87). The range is 0.0 to 1.0. The default value is 1.0.

Field: Height Factor for Opening Factor <n>

The Height Factor of the rectangular window or door for Opening Factor n. The Height Factor is the opening height divided by the window or door height (see Figure 87). The range is 0.0 to 1.0. The default value is 1.0.

Field: Start Height Factor for Opening Factor <n>

The Start Height Factor of the window or door for Opening Factor n. The Start Height Factor is the Start Height divided by the window or door height (see Figure 87). The range is 0.0 to 1.0. The default is 0.

When the opening factor value (as described under the field Window/Door Opening Factor in the AirflowNetwork:Multizone:Surface object) is between two Opening Factor field values, the values of Discharge Coefficient, Width Factor, Height Factor, and Start Height Factor are linearly interpolated.

An IDF example is shown below:

AirflowNetwork:MultiZone:Component:HorizontalOpening

This object specifies the properties of air flow through windows, doors and glass doors (heat transfer subsurfaces defined as a subset of FenestrationSurface:Detailed objects) when they are closed or open. This AirflowNetwork model assumes that these openings are horizontal or close to horizontal and are interzone surfaces. The second and third input fields are similar to those for AirflowNetwork:MultiZone:Surface:Crack, when the window or door is closed, but additional information is required to describe the air flow characteristics when the window or door is open. This additional information is specified in the last two input fields. The airflow across the opening consists of two types of flows: forced and buoyancy. The forced flow is caused by the pressure difference between two zones, while the buoyancy flow only occurs when the air density in the upper zone is greater than the air density in the lower zone. This opening also allows for the possibility of two-way flow when forced and buoyancy flows co-exist. This object's openness can also be modulated based on the same opening factor control as an AirflowNetwork:MultiZone:Component:DetailedOpening object. However, the opening factor is only applied to the subsurface width. The opening width is equal to opening factor multiplied by the subsurface width.

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

Field: Name

This is a name for this AirflowNetwork:MultiZone:Component:HorizontalOpening object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Air Mass Flow Coefficient When Opening is Closed

The value of the air mass flow coefficient, $C_{Q,unit\ length}$, in the horizontal opening air flow equation. It has units of kg/s-m at 1Pa. The temperature correction factor is not applied to the mass flow calculation. This is a required input field and the entered value must be greater than zero.

Field: Air Mass Flow Exponent When Opening is Closed

The value of the exponent, n , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.

Field: Sloping Plane Angle

This numeric field is used to represent the angle between the horizontal plane and a sloped plane under the horizontal opening. Sloping plane angle = 90 is equivalent to fully open. The valid range is >0 to 90, with the default value being 90.

Field: Discharge Coefficient

This numeric field is used to input the discharge coefficient. This is a required field and the entered value must be greater than zero.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Component:HorizontalOpening,
    HrOpen,                      !- Name
    0.001,                        !- Air Mass Flow Coefficient When Opening is Closed {kg/s-m}
    0.667,                        !- Air Mass Flow Exponent When Opening is Closed {dimensionless}
    90.0,                         !- Sloping Plane Angle
    0.2;                          !- Discharge Coefficient
```

AirflowNetwork:MultiZone:Component:SimpleOpening

This object specifies the properties of air flow through windows, doors and glass doors (heat transfer subsurfaces) when they are closed or open. The AirflowNetwork model assumes that open windows or doors are vertical or close to vertical. The second and third fields are similar to those for AirflowNetwork:MultiZone:Surface:Crack, when the window or door is closed, but additional information is required to describe the air flow characteristics when the window or door is open. This additional information is specified in the last two fields. Compared to the object AirflowNetwork:MultiZone:Component:DetailedOpening, which requires more inputs at different opening factors, this object needs comparatively less inputs. For this reason it is called a simple opening. This opening also allows for the possibility of two-way flow due to temperature and resulting density differences. Therefore, it is possible to have a positive pressure difference at the top of the opening, and a negative pressure difference at the bottom (or vice versa) when the neutral height is between the bottom and top heights of the associated surface. This object's openness can also be modulated based on the same opening factor control as an AirflowNetwork:MultiZone:Component:DetailedOpening object. However, the opening factor is only applied to the subsurface width. The opening width is equal to opening factor multiplied by the subsurface width.

A subsurface multiplier may be used to represent multiple subsurfaces and calculates total air flow when the subsurface (window, glassdoor, or door) is either closed or open. The total airflow across the surface is equal to the airflow based on the surface geometry multiplied by the subsurface multiplier.

Field: Name

This is a name for this AirflowNetwork:MultiZone:Component:SimpleOpening object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Air Mass Flow Coefficient When Opening is Closed

The value of the air mass flow coefficient, $C_{Q, \text{unit length}}$, in the simple opening air flow equation. It has units of kg/s-m at 1Pa. The temperature correction factor is not applied for mass flow calculation.

Field: Air Mass Flow Exponent When Opening is Closed

The value of the exponent, n , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65.

Field: Minimum Density Difference for Two-Way Flow

This numeric field is used to input the minimum density difference above which two-way flow may occur due to stack effect. Density differences less than this value result in one-way flow. The minimum value for this field is greater than zero.

Field: Discharge Coefficient

This numeric field is used to input the discharge coefficient. This value must be greater than zero.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Component:SimpleOpening,
WiOpen2,                               !- Simple Opening Name
0.001,                                !- Air Mass Flow Coefficient When Opening Is Closed {kg/s-m}
0.650,                                !- Air Mass Flow Exponent When Opening Is Closed {dimensionless}
0.0001,                               !- Minimum density difference for two-way flow (kg/m3)
1.0;                                   !- Discharge coefficient (dimensionless)
```

AirflowNetwork:MultiZone:Component:ZoneExhaustFan

This object specifies the properties of air flow through an exterior heat transfer surface with a zone exhaust fan. The zone exhaust fan turns on or off based on the availability schedule defined in the corresponding Fan:ZoneExhaust object. When the exhaust fan mass flow rate is greater than zero, the airflow network model treats this object as a constant volume fan. When the fan is off based on the availability schedule, the model treats this object as a crack.

When the fan is on, the air mass flow rate modeled for the airflow network is based on the value defined in the Maximum Flow Rate field of the Fan:ZoneExhaust object. The airflow direction is from the corresponding zone to outdoors.

When the fan is off, the following power law form is used that gives air flow through the crack as a function of the pressure difference across the crack:

$$Q = (\text{Crack Factor}) * C_T * C_Q (\Delta P)^n$$

Where

Q = air mass flow (kg/s)

C_Q = air mass flow coefficient (kg/s-Pa^n @ 1 Pa)

C_T = reference condition temperature correction factor (dimensionless)

ΔP = pressure difference across crack (Pa)

n = air flow exponent (dimensionless)

$$C_T = \left[\frac{\rho_o}{\rho} \right]^{n-1} \left[\frac{V_o}{V} \right]^{2n-1}$$

where

ρ = Air density at the specific air temperature and humidity ratio conditions [kg/m^3]

V = Air kinetic viscosity at the specific air temperature condition [m^2/s]

ρ_0 = Air density at the reference air conditions provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [kg/m³]

ν_0 = Air kinetic viscosity at the reference air temperature provided by the object AirflowNetwork:MultiZone:ReferenceCrackConditions specified in the field Reference Crack Conditions [m²/s]

Note: The correction factor shown above is used when the exhaust fan is off. The airflow direction is based on the pressure difference between the zone and outdoors.

Field: Name

This is the name for this instance of the AirflowNetwork:MultiZone:Component:ZoneExhaustFan object. This name must be the same name defined in the Fan:ZoneExhaust object. It is referenced by an AirflowNetwork:Multizone:Surface object.

Field: Air Mass Flow Coefficient When the Zone Exhaust Fan is Off at Reference Conditions

The value of the air mass flow coefficient, C_Q , in the crack air flow equation. It has units of kg/s at 1Pa. This value must be greater than zero. The value is used when the fan is off.

Field: Air Mass Flow Exponent When the Zone Exhaust Fan is Off

The value of the exponent, n , in the crack air flow equation. The valid range is 0.5 to 1.0, with the default value being 0.65. The value is used when the fan is off.

Field: Reference Crack Conditions

The name of the AirflowNetwork:MultiZone:ReferenceCrackConditions object which specifies the conditions under which the air mass flow coefficient was measured. If the user omits this field and only one AirflowNetwork:MultiZone:ReferenceCrackConditions object is defined in the input data file, then those reference crack conditions will be used. If the user omits this field and either zero or more than one AirflowNetwork:MultiZone:ReferenceCrackConditions objects are defined in the input data file, then the default conditions for the AirflowNetwork:Multizone: Reference Crack Conditions object will be used.

An IDF example is shown below:

```
AirflowNetwork:MultiZone:Component:ZoneExhaustFan,
  Zone3 Exhaust Fan,      !- Name
  0.01,      !- Air Mass Flow Coefficient When the Zone Exhaust Fan is Off at Reference Conditions {kg/s}
  0.667;    !- Air Mass Flow Exponent When the Zone Exhaust Fan is Off{dimensionless}
  ReferenceCrackConditions; !- Reference Crack Conditions
```

AirflowNetwork:MultiZone:ExternalNode

External nodes in the AirflowNetwork model define environmental conditions outside of the building. These conditions include wind pressure coefficients that vary from façade to façade and can be highly dependent on the building geometry.

AirflowNetwork:MultiZone:ExternalNode objects do **not** have to be entered if Wind Pressure Coefficient Type = SurfaceAverageCalculation in the AirflowNetwork:SimulationControl object.

Field: Name

The external node name is associated with a particular building façade. This name is referenced by the External Node Name field of an AirflowNetwork:MultiZone:WindPressureCoefficientValues object (which gives wind pressure

coefficients for the façade as a function of angle of wind incident on the façade) and by the External Node Name field of an AirflowNetwork:MultiZone:Surface object.

Field: External Node Height

Designates the reference height, in meters, used to calculate relative pressure. The default value is 0 meters.

Field: Wind Pressure Coefficient Values Object Name

The name of a specific AirflowNetwork:MultiZone:WindPressureCoefficientValues object (which gives wind pressure coefficients for the façade as a function of angle of wind incident on the façade).

IDF examples are provided below:

```

AirflowNetwork:MultiZone:ExternalNode,
  NFacade,
    !- Name
  1.524,
    !- External Node Height {m}
  NFacade_WPCValue;
    !- Wind Pressure Coefficient Values Object Name

    !- External Node Height {m}
  EFacade_WPCValue;
    !- Wind Pressure Coefficient Values Object Name

AirflowNetwork:MultiZone:ExternalNode,
  SFacade,
    !- Name
  1.524,
    !- External Node Height {m}
  SFacade_WPCValue;
    !- Wind Pressure Coefficient Values Object Name

AirflowNetwork:MultiZone:ExternalNode,
  WFacade,
    !- Name
  1.524,
    !- External Node Height {m}
  WFacade_WPCValue;
    !- Wind Pressure Coefficient Values Object Name

AirflowNetwork:MultiZone:ExternalNode,
  Horizontal,
    !- Name
  3.028,
    !- External Node Height {m}
Horizontal_WPCValue;
    !- Wind Pressure Coefficient Values Object Name

```

AirflowNetwork:MultiZone:WindPressureCoefficientArray

The reference height and wind directions are first specified under the AirflowNetwork:MultiZone:WindPressureCoefficientArray object. The user may specify up to 36 different wind directions in ascending order. These are then referenced by AirflowNetwork:MultiZone:WindPressureCoefficientValues objects defined for each AirflowNetwork:MultiZone:ExternalNode.

The AirflowNetwork:MultiZone:WindPressureCoefficientArray object is unique and needs to be entered only if Wind Pressure Coefficient Type = INPUT in the AirflowNetwork:SimulationControl object. If Wind Pressure Coefficient Type = SurfaceAverageCalculation, this object is not required.

Field: Name

The name of this AirflowNetwork:MultiZone:WindPressureCoefficientArray object. This name is referenced by each AirflowNetwork:MultiZone:WindPressureCoefficientValues object which, for each AirflowNetwork:MultiZone:ExternalNode, gives the wind pressure coefficients at each of the wind directions listed in the AirflowNetwork:MultiZone:WindPressureCoefficientArray. This name is also referenced by the AirflowNetwork:SimulationControl object, indicating that this AirflowNetwork:MultiZone:WindPressureCoefficientArray and the pressure coefficients in the

associated AirflowNetwork:MultiZone:WindPressureCoefficientValues objects will be used in the air flow simulation.

Field: Wind Direction 1-Wind Direction N

Each field references the wind direction corresponding to the first through the Nth WPC value in each of the AirflowNetwork:MultiZone:WindPressureCoefficientValues objects. *N* can be as high as 36.

An IDF example is provided below:

```
AirflowNetwork:MultiZone:WindPressureCoefficientArray,
  Every 30 Degrees,      !- WPC Array Name
  0,                      !- Wind Direction #1 {deg}
  30,                     !- Wind Direction #2 {deg}
  60,                     !- Wind Direction #3 {deg}
  90,                     !- Wind Direction #4 {deg}
  120,                    !- Wind Direction #5 {deg}
  150,                    !- Wind Direction #6 {deg}
  180,                    !- Wind Direction #7 {deg}
  210,                    !- Wind Direction #8 {deg}
  240,                    !- Wind Direction #9 {deg}
  270,                    !- Wind Direction #10 {deg}
  300,                    !- Wind Direction #11 {deg}
  330;                   !- Wind Direction #12 {deg}
```

AirflowNetwork:MultiZone:WindPressureCoefficientValues

This object specifies up to 36 wind pressure coefficients (WPCs) for an AirflowNetwork:MultiZone:ExternalNode. These coefficients are defined for each of the wind directions defined in the unique AirflowNetwork:MultiZone:WindPressureCoefficientArray object. In the air flow calculation, interpolation of the specified WPC values is done for time-step values of wind direction.

AirflowNetwork:MultiZone:WindPressureCoefficientValues objects need to be entered only if the Wind Pressure Coefficient Type = INPUT in the AirflowNetwork:SimulationControl object. If Wind Pressure Coefficient Type = SurfaceAverageCalculation, this object is not required and is not used.

Field: Name

The name of this WindPressureCoefficientValues object. This name can be referenced by multiple AirflowNetwork:MultiZone:ExternalNode objects.

Field: WindPressureCoefficientArray Name

Name of the associated AirflowNetwork:MultiZone:WindPressureCoefficientArray, which lists the wind direction corresponding to each wind pressure coefficient value in this AirflowNetwork:MultiZone:WindPressureCoefficientValues object.

Field: Wind Pressure Coefficient Value 1 to Wind Pressure Coefficient Value N

The WPC (wind pressure coefficient) value for the building façade indicated by the External Node Name field above. This WPC value corresponds to the first wind direction in the AirflowNetwork:MultiZone:WindPressureCoefficientArray. Note that WPC values can be positive, negative or zero.

Obtaining WPC values

WPC values can be obtained from wind tunnel measurements, CFD calculations, or from published values for different building shapes.

For **rectangular buildings** EnergyPlus will automatically calculate surface-averaged Cp values for the walls and roof of the building if you specify Wind Pressure Coefficient Type =

SurfaceAverageCalculation in the AirflowNetwork:SimulationControl object. In this case you do not have to enter any AirflowNetwork:MultiZone:WindPressureCoefficientValues objects.

Wind pressure coefficients are reported in the eplusout.eio either from inputs using “INPUT” as the choice for the Wind Pressure Coefficient Type field defined in the AirflowNetwork:SimulationControl object, or from internal calculation using SurfaceAverageCalculation as the choice for the Wind Pressure Coefficient Type field defined in the same object. Below is an output example from the eplusout.eio file:

```

```

The previous sections of this AirflowNetwork model discussion describe input objects used for multizone airflow calculations. The following sections describe input objects used for air distribution system simulations. These objects work when control option “MultiZone with Distribution” or “MultiZone with Distribution Only During Fan Operation” is defined in the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object.

The first section presents the input object for distribution system nodes. Although thermal zones are required to perform air distribution system simulations, the thermal zones are already defined in the multizone input section (described previously), so that there is no need to repeat the inputs for thermal zones when modeling an air distribution system. The same is also true for surface air leakage. This section has only one object: AirflowNetwork:Distribution:Node.

AirflowNetwork:Distribution:Node

The AirflowNetwork:Distribution:Node object is used to represent air distribution system nodes for the AirflowNetwork model. The EnergyPlus nodes defined in an AirLoopHVAC are a subset of the nodes used to simulate the distribution system using the AirflowNetwork model. For example, the inlet node of a fan and the outlet node of a coil defined in an AirLoopHVAC must be defined as nodes using the AirflowNetwork:Distribution:Node object. A set of EnergyPlus Zone Equipment nodes is also a subset of the AirflowNetwork:Distribution:Nodes. For example, zone inlet and outlet nodes must be defined as nodes using the AirflowNetwork:Distribution: Node object. In addition, although mixers and

splitters are defined as objects with inlet and outlet nodes within EnergyPlus, the AirflowNetwork:Distribution:Node object treats mixers and splitters as single nodes. The node objects are referenced by AirflowNetwork:Distribution:Linkage objects.

In summary, all nodes used to define an AirLoopHVAC (except splitters, mixers, and outdoor air systems which are treated as single nodes) and its connections to a thermal zone must be specified as AirflowNetwork:Distribution:Nodes. If distribution system air leaks are to be modeled, additional AirflowNetwork:Distribution:Nodes may be defined along with AirflowNetwork:Distribution:Components (e.g., leak or leak ratio) to define the air leakage characteristics.

Note: Supply and return leaks are not allowed in an AirLoopHVAC. They can only be modeled in the Zone Equipment Loop (i.e., return leaks may be modeled between the zone return node and the zone mixer inlet or the zone mixer outlet and the zone equipment loop outlet; and supply leaks may be modeled between the zone equipment loop inlet and the AirLoopHVAC:ZoneSplitter inlet node or the AirLoopHVAC:ZoneSplitter outlet node and the zone supply node).

Field: Name

The name of an air distribution system node. This node name is referenced by an AirflowNetwork:Distribution:Linkage and in the output listing. Each node should have a unique name within the AirflowNetwork:Distribution:Node objects (however, the node name may be used elsewhere as regular EnergyPlus node names such as the fan inlet node or coil outlet node).

Field: Component Name or Node Name

Designates node names defined in another EnergyPlus object, so that the AirflowNetwork:Distribution:Node object is able to get input parameters and node conditions from the associated EnergyPlus node or object. The actual node name is entered here and represents a node already defined in an AirLoopHVAC or zone equipment loop. This field is left blank if the EnergyPlus Node Type field below is entered as Mixer, Splitter, Outdoor air System, or Other.

Field: Component Object Type or Node Type

This choice field distinguishes the node type for the EnergyPlus node or object name defined above. Five node types are available:

- **AirLoopHVAC:ZoneMixer:** Represents an AirLoopHVAC:ZoneMixer object defined in EnergyPlus
- **AirLoopHVAC:ZoneSplitter:** Represents an AirLoopHVAC:ZoneSplitter object defined in EnergyPlus
- **AirLoopHVAC:OutdoorAirSystem:** Represents an AirLoopHVAC:OutdoorAirSystem object used in EnergyPlus
- **OAMixerOutdoorAirStreamNode:** Represents an external node name specified as an Outdoor Air Stream Node Name in the OutdoorAir:Mixer object when the AirLoopHVAC:OutdoorAirSystem object is used.
- **OutdoorAir:NodeList:** Represents an external node name defined in the OutdoorAir:NodeList object when the AirLoopHVAC:OutdoorAirSystem object and an exhaust energy recovery system (air-to-air heat exchanger) are used.
- **OutdoorAir:** Represents an external node name defined in the OutdoorAir:Node object when the AirLoopHVAC:OutdoorAirSystem and an exhaust energy recovery system (air-to-air heat exchanger) are used.
- **Other:** Represents a type not already defined above.

Note: Both the OutdoorAir:NodeList and OutdoorAir:Node node types represent a node to outdoor air conditions. Either one of these node types can be used to represent an external node when an air-to-air heat exchanger is used to recover energy from the exhaust air stream as part of an AirLoopHVAC:OutdoorAirSystem object. Node type OAMixerOutdoorAirStreamNode does not represent an external node when an OutdoorAir:NodeList or OutdoorAir:Node object is specified. If no exhaust heat recovery system (i.e., air-to-air heat exchanger) is specified in the AirLoopHVAC:OutdoorAirSystem, the node type OAMixerOutdoorAirStreamNode represents an external node.

Field: Node Height

Designates the reference height in meters used to calculate relative pressure. The default value is 0 meters.

IDF examples are provided below:

```
AirflowNetwork:Distribution:Node,
  EquipmentInletNode,      !- Name
  Zone Equipment Inlet Node, !- Component Name or Node Name
  Other,                  !- Component Object Type or Node Type

```

The next section describes AirflowNetwork Distribution Components, with 7 available types listed below. All required fields for each component represent a relationship between pressure difference and airflow. The components are referenced in AirflowNetwork:Distribution:Linkage objects.

- AirflowNetwork:Distribution:Component:Leak
- AirflowNetwork:Distribution:Component:LeakageRatio
- AirflowNetwork:Distribution:Component:Duct
- AirflowNetwork:Distribution:Component:ConstantVolumeFan
- AirflowNetwork:Distribution:Component:Coil
- AirflowNetwork:Distribution:Component:HeatExchanger
- AirflowNetwork:Distribution:Component:TerminalUnit
- AirflowNetwork:Distribution:Component:ConstantPressureDrop

AirflowNetwork:Distribution:Component:Leak

This component may be also called a power law component and is used to represent a supply or return air leak in an air distribution system. Its relationship between pressure difference and airflow may be expressed as:

$$\dot{m} = C_T C (\Delta P)^n$$

where

\dot{m} = Air mass flow rate through the component [kg/s]

C = Air mass flow coefficient (kg/s at 1 Pa pressure difference)

ΔP = Total pressure loss across the element [Pa]

n = Air mass flow exponent

C_T = Temperature correction factor

$$C_T = \left[\frac{\rho_o}{\rho} \right]^{n-1} \left[\frac{V_o}{V} \right]^{2n-1}$$

where

ρ = Air density at the specific air temperature and humidity ratio conditions [kg/m³]

V = Air kinetic viscosity at the specific air temperature condition [m²/s]

ρ_o = Air density at air conditions of 20°C, 0 kg/kg and 101325 Pa [kg/m³]

V_o = Air kinetic viscosity at an air temperature of 20°C [m²/s]

Note: The correction factor shown above is use for this particular component as specified.

Field: Name

A unique name identifying a supply or return air leak in an air distribution system. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component leak.

Field: Air Mass Flow Coefficient

This numeric field is defined as the air mass flow coefficient at 1 Pa pressure difference across this component. Valid entries must be greater than zero.

Field: Air Mass Flow Exponent

This numeric field is defined as the pressure difference exponent across the component. Valid entries are from 0.5 to 1.0, with the default value being 0.65.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:Leak,
  MainSupplyLeak,           !- Name of Supply or Return Leak
  0.0001,                  !- Air Mass Flow Coefficient {kg/s}
  0.65;                   !- Air Mass Flow Exponent {dimensionless}

AirflowNetwork:Distribution:Component:Leak,
  ZoneSupplyLeak,          !- Name of Supply or Return Leak
  0.01,                    !- Air Mass Flow Coefficient {kg/s}
  0.65;                   !- Air Mass Flow Exponent {dimensionless}
```

AirflowNetwork:Distribution:Component:LeakageRatio

The leakage ratio component is generally used to define supply and return leaks with respect to a constant fan flow. This object requires 5 inputs. The relationship between pressure and airflow may be expressed as a power law element:

$$\dot{m} = C_{equ} (\Delta P)^n$$

where

ρ = Air density [kg/m³]

ΔP = Total pressure loss across the element [Pa]

n = Air mass flow exponent

C_{equ} = Equivalent air mass flow coefficient

$$C_{equ} = r * Q_r * \rho * (\Delta P_r)^{-n}$$

where

r = Effective leakage ratio [dimensionless]

Q_r = Maximum airflow rate [m³/s]

ΔP_r = Reference pressure difference [Pa]

n = Air mass flow exponent [dimensionless]

Field: Name

A unique name identifying a supply or return air leak (ratio with respect to the constant volume fan flow rate) in an air distribution system. This unique name will be referenced in an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Effective Leakage Ratio

This numeric field is used to input the effective leakage ratio. This value must be greater than zero and less than or equal to 1. The effective leakage ratio is used to characterize supply and return leaks with respect to the constant fan flow (supply or return air leak flow rate divided by the maximum air flow rate for the fan).

Field: Maximum Flow Rate

This numeric field is used to input the maximum flow rate for a constant volume fan [m³/s]. This value must be greater than 0 m³/s.

Field: Reference Pressure Difference

This numeric field is used to input the reference pressure difference [Pa]. This value must be greater than 0 Pa.

Field: Air Mass Flow Exponent

This numeric field is used to input the pressure difference exponent. The value of the exponent can be from 0.5 to 1.0, with the default value being 0.65.

Note: The reference pressure difference is defined as the difference between pressures of originate and terminate nodes for supply and return leaks. In general, it may require that a simulation be performed with an initial guess for reference pressure difference using design day conditions. After obtaining pressures at the leakage nodes, more realistic reference pressure differences can be entered. It should be pointed out that since pressures at the nodes vary with temperature and other conditions, the effective leakage ratio is only an estimate. In other words, the exact leakage ratio may not be available.

An IDF example is provided below:

```

AirflowNetwork:Distribution:Component:LeakageRatio,
Zone1ELA,
0.043527,
1.0,
4.0,
0.65;
      !- Name of Effective Leakage Ratio
      !- Effective Leakage Ratio {dimensionless}
      !- Maximum Flow Rate {m3/s}
      !- Reference Pressure Difference {Pa}
      !- Air Mass Flow Exponent {dimensionless}

```

AirflowNetwork:Distribution:Component:Duct

This object represents a duct component and requires 9 input fields, one alpha field and 8 numeric fields. The relationship between pressure and airflow across the component may be expressed as (2001 ASHRAE Handbook of Fundamentals, Chapter 34):

$$\dot{m} = \sqrt{\frac{2\rho A^2 \Delta P}{fL/D + \sum C_d}}$$

where

\dot{m} = Mass flow rate of air through the component [kg/s]

ρ = Air density [kg/m³]

A = Cross sectional area [m²]

ΔP = Total pressure loss across the component [Pa]

L = Duct length [m]

D = Hydraulic diameter [m]

C_d = Dynamic loss coefficient due to fitting [dimensionless]

f = Friction factor

The friction factor can be calculated using the nonlinear Colebrook equation (ASHRAE Handbook of Fundamentals, 1997. p. 2.9, Eq. 29b)

$$\frac{1}{\sqrt{f}} = 1.44 + 2 * \log\left(\frac{D}{\varepsilon}\right) - 2 * \log\left(1 + \frac{9.3}{Re * \varepsilon / D * \sqrt{f}}\right)$$

where

ε = Surface roughness [m]

Re = Reynolds number = $\rho V D / \mu$

Field: Name

A unique name for an AirflowNetwork duct component in an air distribution system. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Duct Length

This numeric field is used to input duct length [m]. This value must be greater than zero.

Field: Hydraulic Diameter

This numeric field is used to input hydraulic diameter, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]
 A = Duct cross sectional area [m^2]
 P = Perimeter of cross section [m]

Field: Cross Section Area

This numeric field is used to input cross section area [m^2]. The model assumes that this element has no area change along its length. Otherwise, effective cross sectional area is required.

Field: Surface Roughness

This numeric field is used to input surface roughness [m]. This value must be greater than zero, and the default value is 0.0009 m.

Field: Coefficient for Local Dynamic Loss Due to fitting

This numeric field is defined as a coefficient for dynamic loss [dimensionless]. It represents dynamic loss due to fittings (such as an elbow).

Field: Overall Heat Transmittance Coefficient (U-Factor) from Air to Air

This numeric field is defined as the overall heat transmittance coefficient (U value, $W/m^2\cdot K$) from air to air, including film coefficients at both surfaces.

Field: Overall Moisture Transmittance Coefficient from Air to Air

This numeric field is defined as the overall moisture transmittance coefficient (kg/m^2) from air to air, including film coefficients at both surfaces.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:Duct,
  MainTrunk1,                               ! - Name of Duct Component
  3.0,                                     ! - Duct Length {m}
  0.6,                                     ! - Hydraulic Diameter {m}
  0.2827,                                  ! - Cross Section Area {m2}
  0.0009,                                  ! - Surface Roughness {m}
  0.01,                                     ! - Coefficient for local dynamic loss due to fitting {dimensionless}
  0.772,                                    ! - Overall heat transmittance coefficient (U value) from air to air
  ! - {W/m2-K}
  0.0001;                                   ! - Overall moisture transmittance coefficient from air to air {kg/m2}
```

AirflowNetwork:Distribution:Component:ConstantVolumeFan

This component represents a constant volume fan in the air distribution system (AirLoopHVAC). The air flow rate and air conditions (temperature and humidity) are obtained from the associated Fan:ConstantVolume or Fan:OnOff object.

Field: Fan Name

The name identifying an AirflowNetwork constant volume fan in an air distribution system. This name must be the same as the name of the associated Fan:ConstantVolume or Fan:OnOff object. This name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Supply Fan Object Type

This choice field defines the type of fan. The only valid choices are Fan:OnOff and Fan:ConstantVolume, with the default being Fan:ConstantVolume. Both cycling and continuous fan operating modes are allowed for Fan:OnOff. Only the continuous fan operating mode is allowed for Fan:ConstantVolume.

Note: Make sure that the volumetric air flow rates for the fan, coils, and parent components (e.g., unitary system or furnace) are the same so that fan energy and air distribution system losses/gains are properly calculated.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:ConstantVolumeFan,
Supply Fan 1,                                     !- Name of Constant Volume Fan
Fan:ConstantVolume;   !- Supply fan type
```

AirflowNetwork:Distribution:Component:Coil

This component represents a cooling or heating coil. The main purpose for this object is to get calculated values (air flow and temperature/humidity conditions) from the associated coil models.

Field: Coil Name

The name identifying an AirflowNetwork cooling coil or heating coil defined in an air loop. This name must be the same name as the associated coil object. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Coil Object Type

This field requires input of the coil type used in the AirflowNetwork model. The available choices are:

- Coil:Cooling:DX:SingleSpeed
- Coil:Heating:Gas
- Coil:Heating:Electric
- Coil:Heating:DX:SingleSpeed
- Coil:Cooling:Water
- Coil:Heating:Water
- Coil:Cooling:Water:DetailedGeometry
- Coil:Cooling:DX:TwoStageWithHumidityControlMode
- Coil:Cooling:DX:MultiSpeed
- Coil:Heating:DX:MultiSpeed
- Coil:Heating:Desuperheater

Field: Air Path Length

This numeric field is used to input air path length for the coil [m]. This value must be greater than 0 meters.

Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter of a coil's air path, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]

A = Duct cross section area [m^2]

P = Perimeter of cross section [m]

For this component, the relationship between airflow and pressure is similar to the component AirflowNetwork:Distribution:Component:Duct. However, the model assumes very small surface roughness (10^{-4}) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings is ignored.

Note: Make sure that the volumetric air flow rates for the fan, coils, and parent components (e.g., unitary system or furnace) are the same so that fan energy and air distribution system losses/gains are properly calculated.

An IDF example is provided below:

```

AirflowNetwork:Distribution:Component:Coil,
  ACDXCoil 1,                               !- Name of Associated EnergyPlus Coil
  Coil:Cooling:DX:SingleSpeed,               !- EnergyPlus Coil Type
  0.1,                                         !- Air Path Length {m}
  1.00;                                        !- Air Path Hydraulic Diameter {m}

AirflowNetwork:Distribution:Component:Coil,
  HP Heating Coil 1,                         !- Name of Associated EnergyPlus Coil
  Coil:Heating:DX:SingleSpeed,                !- EnergyPlus Coil Type
  0.1,                                         !- Air Path Length {m}
  1.00;                                        !- Air Path Hydraulic Diameter {m}

```

AirflowNetwork:Distribution:Component:HeatExchanger

This component represents an air-to-air heat exchanger typically used in combination with a cooling coil to enhance dehumidification or in an outside air system to recover energy from exhaust air to pretreat incoming outdoor ventilation air. The cooling coils with enhanced dehumidification are defined in the two objects CoilSystem:Cooling:DX:HeatExchangerAssisted and CoilSystem:Cooling:Water:HeatExchangerAssisted using one of three heat exchanger objects specified below. The exhaust air energy recovery system also has the same restriction using the one of three heat exchanger objects. The main purpose for this object is to obtain calculated values (air flow and temperature/humidity conditions) from the associated heat exchanger models for the airflow network calculations.

Field: Heat Exchanger Name

The name identifying an AirflowNetwork heat exchanger defined in an air loop. This name must be the same name that is used in the associated heat exchanger object. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Heat Exchanger Object Type

This field requires input of the heat exchanger type. The available choices are:

- HeatExchanger:AirToAir:FlatPlate
- HeatExchanger:AirToAir:SensibleAndLatent
- HeatExchanger:Desiccant:BalancedFlow

Field: Air Path Length

This numeric field is used to input air path length for the heat exchanger coil [m]. This value must be greater than 0 meters.

Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter of a heat exchanger coil's air path, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]

A = Duct cross section area [m²]

P = Perimeter of cross section [m]

For this component, the relationship between airflow and pressure is similar to the component AirflowNetwork:Distribution:Component:Duct. However, the model assumes very small surface roughness (10⁻⁴) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings are ignored.

Note: When a heat exchanger is used as a component of either CoilSystem:Cooling:DX:HeatExchangerAssisted or CoilSystem:Cooling:Water:HeatExchangerAssisted, the heat exchanger acts as two components in an air primary loop. For example, an air-to-air heat exchanger has a component connected to the supply air side (equivalent to a supply coil) and a component connected to exhaust air side (equivalent to an exhaust coil). The desiccant heat exchanger has a component connected to regeneration air side (equivalent to a regeneration air coil) and a component connected to process air side (equivalent to a process air coil). Therefore, each air-to-air heat exchanger used in this configuration requires two linkage objects (instead of only one linkage object as required for other AirflowNetwork components).

When a heat exchanger is used in an exhaust air energy recovery system (i.e., in an AirLoopHVAC:OutdoorAirSystem object to recover waste heat from exhaust air to pretreat incoming outdoor ventilation air), the heat exchanger is treated as a single component. The AirflowNetwork model only connects the two nodes associated with the incoming outdoor ventilation air, while the two exhaust nodes are not defined as part of the AirflowNetwork model. Therefore, each heat exchanger component used in an exhaust air energy recovery system has only one linkage object, similar to AirflowNetwork coil components.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:HeatExchanger,
  OA Heat Recovery 1,           !- HeatExchanger Name
  HeatExchanger:AirToAir:SensibleAndLatent, !- HeatExchanger Object Type
  0.1,                         !- Air Path Length {m}
  1.00;                        !- Air Path Hydraulic Diameter {m}

AirflowNetwork:Distribution:Component:HeatExchanger,
  Desiccant Heat Exchanger 1, !- HeatExchanger Name
  HeatExchanger:Desiccant:BalancedFlow, !- HeatExchanger Object Type
  0.1,                         !- Air Path Length {m}
  1.00;                        !- Air Path Hydraulic Diameter {m}
```

AirflowNetwork:Distribution:Component:TerminalUnit

This component represents a terminal unit for reheating the incoming supply air. The main purpose is to get calculated values from the terminal unit models.

Field: Terminal Unit Name

A name identifying an AirflowNetwork terminal unit defined in a zone equipment list. This name must be the same as the associated terminal unit object. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Terminal Unit Object Type

This field requires input of the terminal unit type used in the AirflowNetwork model. The only available type is AirTerminal:SingleDuct:ConstantVolume:Reheat.

Field: Air Path Length

This numeric field is used to input the air path length for the terminal unit [m]. This value must be greater than 0 meters.

Field: Air Path Hydraulic Diameter

This numeric field is used to input hydraulic diameter for the terminal unit's air path, which is defined as:

$$D_h = \frac{4A}{P}$$

where

D_h = Hydraulic diameter [m]

A = Duct cross section area [m^2]

P = Perimeter of cross section [m]

It should be noted that the relationship for this component between airflow and pressure is similar to the component AirflowNetwork:Distribution:Component:Duct. However, the model assumes very small surface roughness (10^{-4}) and no local dynamic loss due to fittings for this component. Therefore, this component only requires two numerical fields. Heat and moisture exchange from surroundings is ignored.

Note: The AirflowNetwork:Distribution:Component:TerminalUnit object is used to represent an AirTerminal:SingleDuct:ConstantVolume:Reheat object in an AirflowNetwork simulation. The AirflowNetwork:Distribution:Component:TerminalUnit should not be used to represent any other air terminal unit types. When the ZoneHVAC:EquipmentList object specifies an Air:Terminal:SingleDuct:Uncontrolled object, the AirflowNetwork:Distribution:Component:Duct object should be used instead.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:TerminalUnit,
  Reheat Zone 1,                                     !- Name of Associated Energyplus Terminal Unit
  AirTerminal:SingleDuct:ConstantVolume:Reheat,      !- EnergyPlus Terminal Unit Type
  0.1,                                              !- Air Path Length {m}
  0.44;                                            !- Air Path Hydraulic Diameter {m}
```

AirflowNetwork:Distribution:Component:ConstantPressureDrop

This component represents a constant pressure drop component. It is generally used to simulate a constant pressure drop filter. The mathematical equation may be written as:

$$\Delta P = const$$

Field: Name

A unique name identifying an AirflowNetwork constant pressure drop component in an air distribution system. This unique name will be referenced by an AirflowNetwork:Distribution:Linkage object to represent a component.

Field: Pressure Difference across the Component

This numeric field is used to input the pressure difference across the element [Pa].

Note: This object should be used with caution. Each node connected to this object cannot be a node for a mixer or splitter, a node in an AirLoopHVAC, or a node in a zone configuration loop. It is recommended that duct components be specified at both ends of this object.

An IDF example is provided below:

```
AirflowNetwork:Distribution:Component:ConstantPressureDrop,  
SupplyCPDComp, ! Name of Constant Pressure Drop Component  
1.0;          ! Pressure Difference Across the Component [Pa]
```

AirflowNetwork:Distribution:Linkage

The AirflowNetwork:Distribution:Linkage represents a connection between two AirflowNetwork:Distribution:Node objects and an AirflowNetwork component defined above. In addition, the relative height from node height to linkage height for each node is required.

Field: Name

The name identifies the linkage for later reference and in the output listing. Each linkage should have a unique name.

Field: Node 1 Name

Designates a node name where airflow starts. The node name should be defined in an AirflowNetwork:Distribution:Node object.

Field: Node 2 Name

Designates a node name where airflow ends. The node name should be defined in an AirflowNetwork:Distribution:Node object.

Field: Component Name

Designates an AirflowNetwork component name associated with the two nodes. The component name should be one of the AirflowNetwork:Distribution:Component... object names.

Field: Thermal Zone Name

Designates a thermal zone where the linkage is located. The information provides the ambient conditions for duct elements to calculate duct conduction losses (only used if component is AirflowNetwork:Distribution:Component:Duct).

An IDF example is provided below:

```

AirflowNetwork:Distribution:Linkage,
Main Link 1,           !- Name of Linkage
EquipmentInletNode,   !- Node 1 Name
SupplyMainNode,        !- Node 2 Name
MainTrunk1,           !- Component Name
Attic Zone;          !- Thermal Zone Name

```

AirflowNetwork Outputs

The AirflowNetwork nodes in the following output variables includes zones defined in AirflowNetwork:Multizone:Zone objects, external nodes defined in AirflowNetwork:MultiZone:ExternalNode objects, and nodes defined in AirflowNetwork:Distribution:Node objects.

The AirflowNetwork linkage used in following output variables includes surfaces defined in AirflowNetwork:Multizone:Surface objects, and linkages defined in AirflowNetwork:Distribution:Linkage objects. The surface linkages represent airflows through surface cracks or openings between two zones or between a zone and outdoors. The distribution linkages represent airflows in an air distribution system.

HVAC,Sum,AirflowNetwork Zone Mixing Mass [kg]
```

The following are reported only when a Fan:OnOff object is used:

```
HVAC,Average,AirflowNetwork Average Zone Pressure [Pa]
HVAC,Average,AirflowNetwork Zone Pressure During ON cycle [Pa]
HVAC,Average,AirflowNetwork Zone Pressure During OFF cycle [Pa]
HVAC,Average,AirflowNetwork Average Mass Flow Rate from Node 1 to 2 [kg/s]
HVAC,Average,AirflowNetwork Average Mass Flow Rate from Node 2 to 1 [kg/s]
HVAC,Average,AirflowNetwork Average Volume Flow Rate from Node 1 to 2 [m³/s]
HVAC,Average,AirflowNetwork Average Volume Flow Rate from Node 2 to 1 [m³/s]
HVAC,Average,AirflowNetwork Surface Average Pressure Difference [Pa]
HVAC,Average,AirflowNetwork Surface Pressure Difference During ON cycle [Pa]
HVAC,Average,AirflowNetwork Surface Pressure Difference During OFF cycle [Pa]
```

AirflowNetwork Node Temperature [C]

This is the AirflowNetwork node temperature output in degrees C. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the temperature when the fan is operating (ON).

AirflowNetwork Node Humidity Ratio [kg/kg]

This is the AirflowNetwork node humidity ratio output in kg/kg. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, this value for AirflowNetwork:Distribution:Node objects reflects the humidity ratio when the fan is operating (ON).

AirflowNetwork Node Total Pressure [Pa]

This is the AirflowNetwork node total pressure in Pa with respect to outdoor barometric pressure. The total pressure is the sum of static pressure, dynamic pressure, and elevation impact at the node's relative height. When a Fan:OnOff object is used and is scheduled to operate in the cycling fan operation mode, the value for AirflowNetwork:Distribution:Node objects reflects the total pressure when the fan is operating (ON). The total pressures for nodes associate with AirflowNetwork:Multizone:Zone objects are reported in different output variables (below).

AirflowNetwork Average Zone Pressure [Pa]

This is the AirflowNetwork average zone total pressure in Pa with respect to outdoor barometric pressure. This output is only available when a Fan:OnOff object is used in the air distribution system. The average zone pressure is weighted by the system fan part-load ratio using the calculated zone pressures during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Average zone pressure = (Zone pressure during on cycle * Part-load ratio) + Zone pressure during off cycle * (1.0 – Part-load ratio)

AirflowNetwork Zone Pressure During ON cycle [Pa]

This is the AirflowNetwork zone total pressure in Pa with respect to outdoor barometric pressure when the air distribution system fan is operating (ON). This output is only available when a Fan:OnOff object is used in the air distribution system. When the fan part-load ratio is equal to 0.0, this pressure value will be zero because the air distribution system is not simulated when the fan is off for the entire timestep.

AirflowNetwork Zone Pressure During OFF cycle [Pa]

This is the AirflowNetwork zone total pressure in Pa with respect to outdoor barometric pressure when the air distribution system fan is not operating (OFF). This output is only available when a Fan:OnOff object is used in the air distribution system. Even if the fan part-load ratio is equal to 1.0, the pressure calculated as if the fan were not operating (OFF) is reported.

AirflowNetwork Wind Pressure [Pa]

This is the AirflowNetwork wind pressure output in Pa. The wind pressure depends on several factors, including wind speed, wind direction, the wind-pressure coefficient (C_p) values for the AirflowNetwork:MultiZone:ExternalNode associated with the heat transfer surface and the site wind conditions.

When Wind Pressure Coefficient Type = “Input” in the AirflowNetwork:SimulationControl object, the output represents external node pressures driven by wind defined in an AirflowNetwork:MultiZone:ExternalNode object. When Wind Pressure Coefficient Type = “SurfaceAverageCalculation” in AirflowNetwork:SimulationControl, the program assumes five external nodes:

- FACADE1 Representing north orientation
- FACADE2 Representing east orientation
- FACADE3 Representing south orientation
- FACADE4 Representing west orientation
- ROOF Representing horizontal orientation

In this case, the output represents the wind pressures for the five external nodes defined above.

AirflowNetwork Mass Flow Rate from Node 1 to 2 [kg/s]

This is the AirflowNetwork linkage mass flow rate output in kg/s in the direction from Node 1 to Node 2. It reports surface airflows through a crack or opening, and through linkages defined in an AirflowNetwork:Distribution:Linkage object. The surface linkage is divided into two types of surfaces, exterior surface and interior surface. Node 1 for an exterior surface linkage is a thermal zone and Node 2 is an external node. The value of AirflowNetwork Mass Flow Rate from Node 1 to 2 represents the flow rate from a thermal zone to outdoors. The flow direction through an interior surface crack or opening is defined from a thermal zone defined by a surface’s Zone Name (Node 1) to an adjacent thermal zone defined by a surface’s OutsideFaceEnvironment (Node 2). For an AirflowNetwork:Distribution:Linkage object, the value represents the air mass flow rate flowing from Node 1 to Node 2.

It should be pointed out that in general, each linkage has one directional flow at any given time, either from Node 1 to 2 or from Node 2 to 1. However, there are three components which may have flows in both directions simultaneously: AirflowNetwork:MultiZone:Component:DetailedOpening, AirflowNetwork:MultiZone:Component:SimpleOpening, and AirflowNetwork:MultiZone:Component:HorizontalOpening.

When a Fan:OnOff object is used, the air mass flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air mass flow rates when the fan is off are zero for the distribution system

air linkage objects. The air mass flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Mass Flow Rate from Node 2 to 1 [kg/s]

This is the AirflowNetwork linkage mass flow rate output in kg/s in the direction from Node 2 to Node 1. It reports airflows from surfaces through a crack or opening, and from linkages defined in an AirflowNetwork:Distribution:Linkage object. Node 1 and Node 2 for a surface or subsurface are defined in the same manner as AirflowNetwork Mass Flow Rate from Node 1 to 2.

When a Fan:OnOff object is used, the air mass flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air mass flow rates when the fan is off are zero for the distribution system air linkage objects. The air mass flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Average Mass Flow Rate from Node 1 to 2 [kg/s]

This is the AirflowNetwork linkage average mass flow rate in kg/s in the direction from Node 1 to Node 2 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used in the air distribution system. The average mass flow rate is weighted by the system fan part-load ratio using the calculated air mass flow rates during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Average surface mass flow rate = (Surface mass flow rate during on cycle * Part-load ratio) + Surface mass flow rate during off cycle * (1.0 – Part-load ratio)

AirflowNetwork Average Mass Flow Rate from Node 2 to 1 [kg/s]

This is the AirflowNetwork linkage average mass flow rate in kg/s in the direction from Node 2 to Node 1 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used in the air distribution system. The average mass flow rate is weighted by the system fan part-load ratio using the calculated air mass flow rates during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

AirflowNetwork Volume Flow Rate from Node 1 to 2 [m^3/s]

This is the AirflowNetwork linkage volume flow rate output in m^3/s in the direction from the Node 1 to Node 2. It is defined in the same manner as AirflowNetwork Mass Flow Rate from Node 1 to 2.

When a Fan:OnOff object is used, the air volume flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air volume flow rates when the fan is off are zero for the distribution system air linkage objects. The air volume flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Volume Flow Rate from Node 2 to 1 [m^3/s]

This is the AirflowNetwork linkage volume flow rate output in m^3/s in the direction from Node 2 to Node 1. It is defined in the same manner as AirflowNetwork Mass Flow Rate from Node 2 to 1.

When a Fan:OnOff object is used, the air volume flow rates reported for the AirflowNetwork:Distribution:Linkage objects are the values when the fan is operating (ON). It is assumed that the air volume flow rates when the fan is off are zero for the distribution system air linkage objects. The air volume flow rates for the AirflowNetwork:Multizone:Surface object are reported in different output variables (below).

AirflowNetwork Average Volume Flow Rate from Node 1 to 2 [m³/s]

This is the AirflowNetwork linkage average volume flow rate in m³/s in the direction from Node 1 to Node 2 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used. The average volume flow rate is weighted by the system fan part-load ratio using the calculated air volume flow rates during the fan on and off periods for the system timestep.

Average surface volume flow rate = (Surface volume flow rate during on cycle * Part-load ratio) + Surface volume flow rate during off cycle * (1.0 – Part-load ratio)

AirflowNetwork Average Volume Flow Rate from Node 2 to 1 [m³/s]

This is the AirflowNetwork linkage average volume flow rate in m³/s in the direction from Node 2 to Node 1 defined in the AirflowNetwork:Multizone:Surface objects. This output is only available when a Fan:OnOff object is used. The average volume flow rate is weighted by the system fan part-load ratio using the calculated air volume flow rates during the fan on and off periods for the system timestep.

AirflowNetwork Linkage Pressure Difference [Pa]

This is the pressure difference across a linkage in Pa. The linkage includes both objects: AirflowNetwork:Multizone:Surface and AirflowNetwork: Distribution:Linkage.

When a Fan:OnOff object is used, the pressure differences reported for the AirflowNetwork:Distribution:Linkage objects are the values calculated when the fan is operating (ON). It is assumed that the pressure differences when the fan is off are zero for the distribution system air linkage objects. The pressure differences defined in the AirflowNetwork:Multizone:Surface are reported in different output variables (below).

AirflowNetwork Surface Average Pressure Difference [Pa]

This is the average pressure difference across a linkage in Pa for the AirflowNetwork:Multizone:Surface objects only when a Fan:OnOff object is used. The average pressure difference is weighted by the system fan part-load ratio using the calculated pressure differences during the fan on and off periods for the system timestep. The system fan part-load ratio is defined as the ratio of the air distribution system mass flow rate (average for the simulation timestep) to the system design mass flow rate.

Surface Average Pressure Difference = (Surface Average Pressure Difference during on cycle * Part-load ratio) + Surface Average Pressure Difference during off cycle * (1.0 - Part-load ratio)

AirflowNetwork Surface Pressure Difference During ON cycle [Pa]

This is the pressure difference across a linkage in Pa for the AirflowNetwork:Multizone:Surface objects only when the air distribution system fan is operating (ON). This output is only available when a Fan:OnOff object is used. When the fan part-load ratio is equal to 0.0, this pressure difference value will be zero because the air distribution system is not simulated when the fan is off for the entire timestep.

AirflowNetwork Surface Pressure Difference During OFF cycle [Pa]

This is the pressure difference across a linkage in Pa for the AirflowNetwork:Multizone:Surface objects only when the air distribution system fan is not operating (OFF). This output is only available when a Fan:OnOff object is used. Even if the fan part-load ratio is equal to 1.0, the pressure difference calculated as if the fan were not operating (OFF) is reported.

Window/Door Venting Opening Factor []

The current time-step value of the venting opening factor for a particular window or door. When the window or door is venting, this is the input value of the opening factor (see AirflowNetwork:Multizone:Surface, Window/Door Opening Factor) times the multiplier for

venting modulation (see description of next output variable, “Opening Factor Multiplier for AirflowNetwork Venting Modulation”). For example, if the input Window/Door opening factor is 0.5 and the modulation multiplier is 0.7, then the value of this output variable will be $0.5 \times 0.7 = 0.35$.

Opening Factor Multiplier for AirflowNetwork Venting Modulation []

This is the multiplier on a window or door opening factor when venting modulation is in effect. See “Modulation of Openings” under AirflowNetwork:Multizone:Zone for a description of how the multiplier is determined.

When modulation is in effect the value of the multiplier is between 0.0 and 1.0. When modulation does not apply the value of the multiplier may be -1.0. When modulation applies but the surface is not venting, the value is -1.0. This is summarized in the following table. In this table, “Zone” means a thermal zone for which AirflowNetwork:Multizone:Zone has been specified. See AirflowNetwork: Multizone:Zone for definition of “Ventilation Control Mode.”

Table 25. Value of opening factor multiplier for different venting conditions.

Is surface in a Zone?	Ventilation Control Mode	Is surface venting?	Value of opening factor multiplier
Yes	Temperature	Yes	0.0 to 1.0
		No	-1.0
	Enthalpy	Yes	0.0 to 1.0
		No	-1.0
	Constant	Yes	1.0
	NoVent	No	-1.0

Inside Temp Setpoint for AirflowNetwork Venting [C]

The time-step value of the venting setpoint temperature for the zone to which the surface belongs. This setpoint is determined from the Vent Temperature Schedule input (ref: AirflowNetwork:Multizone:Zone).

Venting Availability []

A value of 1.0 means venting through the surface can occur if venting control conditions are satisfied. A value of 0.0 means venting through the surface cannot occur under any circumstances. This value is determined by the Venting Availability Schedule input (ref: AirflowNetwork:Multizone:Zone or AirflowNetwork:Multizone: Surface).

AirflowNetwork Infiltration Sensible Gain Rate [W]

The average convective sensible heat gain rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, this reported value is weighted by the system run time fraction using the calculated infiltration sensible gain rate during the system on and off cycles for the reporting period:

Infiltration Sensible Gain Rate = (Infiltration Sensible Gain Rate during on cycle * Run time fraction) + Infiltration Sensible Gain Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Sensible Gain [J]

The average convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature; otherwise, the sensible gain rate is set to 0.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible gain during the system on and off cycles for the reporting period:

$$\text{Infiltration Sensible Gain} = (\text{Infiltration Sensible Gain during on cycle} * \text{Run time fraction}) + (\text{Infiltration Sensible Gain during off cycle} * (1.0 - \text{Run time fraction}))$$

AirflowNetwork Infiltration Sensible Loss Rate [W]

The average convective sensible heat loss rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible loss rate during the system on and off cycles for the reporting period:

$$\text{Infiltration Sensible Loss Rate} = (\text{Infiltration Sensible Loss Rate during on cycle} * \text{Run time fraction}) + (\text{Infiltration Sensible Loss Rate during off cycle} * (1.0 - \text{Run time fraction}))$$

AirflowNetwork Infiltration Sensible Loss [J]

The average convective sensible heat loss, in Joules, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration sensible loss rate during the system on and off cycles for the reporting period:

$$\text{Infiltration Sensible Loss} = (\text{Infiltration Sensible Loss during on cycle} * \text{Run time fraction}) + (\text{Infiltration Sensible Loss during off cycle} * (1.0 - \text{Run time fraction}))$$

AirflowNetwork Infiltration Latent Gain Rate [W]

The average convective latent heat gain rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period, when the outdoor humidity ratio is higher than the zone air humidity ratio.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent gain rate during the system on and off cycles for the reporting period:

$$\text{Infiltration Latent Gain Rate} = (\text{Infiltration Latent Gain Rate during on cycle} * \text{Run time fraction}) + (\text{Infiltration Latent Gain Rate during off cycle} * (1.0 - \text{Run time fraction}))$$

AirflowNetwork Infiltration Latent Gain [J]

The total convective latent heat gain, in Joules, to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent gain during the system on and off cycles for the reporting period:

$$\text{Infiltration Latent Gain} = (\text{Infiltration Latent Gain during on cycle} * \text{Run time fraction}) + (\text{Infiltration Latent Gain during off cycle} * (1.0 - \text{Run time fraction}))$$

AirflowNetwork Infiltration Latent Loss Rate [W]

The average convective latent heat loss rate, in Watts, to the zone air corresponding to the Zone Infiltration Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent loss rate during the system on and off cycles for the reporting period:

Infiltration Latent Loss Rate = (Infiltration Latent Gain Loss Rate during on cycle * Run time fraction) + Infiltration Latent Loss Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Infiltration Latent Loss [J]

The total convective latent heat loss, in Joules, to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated infiltration latent loss during the system on and off cycles for the reporting period:

Infiltration Latent Loss = (Infiltration Latent Gain Loss during on cycle * Run time fraction) + Infiltration Latent Loss during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Gain Rate [W]

The average convective sensible heat gain rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period. The mixing-volume is defined as incoming volume flow from other adjacent zones where the air temperature is higher than the temperature in this zone. For example, there are two zones (Zone 2 and Zone 3) adjacent to this zone (Zone 1). Zone 1 receives airflows from both Zone 2 and Zone 3. The air temperature is 21°C in Zone 1. The air temperatures are 20°C in Zone 2 and 22°C in Zone 3. The sensible gain rate only includes heat gain from Zone 3 with respect to Zone 1. The energy received from Zone 2 is considered as a sensible loss, instead of a gain, because the air temperature in Zone 2 is lower than in Zone 1.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible gain rate during the system on and off cycles for the reporting period:

Mixing Sensible Gain Rate = (Mixing Sensible Gain Rate during on cycle * Run time fraction) + Mixing Sensible Gain Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Loss Rate [W]

The average convective sensible heat loss rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible loss rate during the on and off cycles for the reporting period:

Mixing Sensible Loss Rate = (Mixing Sensible Loss Rate during on cycle * Run time fraction) + Mixing Sensible Loss Rate during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Gain [J]

The total convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible gain during the on and off cycles for the reporting period:

Mixing Sensible Gain = (Mixing Sensible Gain during on cycle * Run time fraction) + Mixing Sensible Gain during off cycle * (1.0 – Run time fraction)

AirflowNetwork Mixing Sensible Loss [J]

The total convective sensible heat loss, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing sensible loss during the on and off cycles for the reporting period:

$$\text{Mixing Sensible Loss} = (\text{Mixing Sensible Loss during on cycle} * \text{Run time fraction}) + \text{Mixing Sensible Loss during off cycle} * (1.0 - \text{Run time fraction})$$

AirflowNetwork Mixing Latent Gain Rate [W]

The average convective latent heat gain rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent gain rate during the on and off cycles for the reporting period:

$$\text{Mixing Latent Gain Rate} = (\text{Mixing Latent Gain Rate during on cycle} * \text{Run time fraction}) + \text{Mixing Latent Gain Rate during off cycle} * (1.0 - \text{Run time fraction})$$

AirflowNetwork Mixing Latent Gain [J]

The total convective latent heat gain, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent gain during the on and off cycles for the reporting period:

$$\text{Mixing Latent Gain} = (\text{Mixing Latent Gain during on cycle} * \text{Run time fraction}) + \text{Mixing Latent Gain during off cycle} * (1.0 - \text{Run time fraction})$$

AirflowNetwork Mixing Latent Loss Rate [W]

The average convective latent heat loss rate, in Watts, to the zone air corresponding to the Zone Mixing Volume averaged over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent loss rate during the on and off cycles for the reporting period:

$$\text{Mixing Latent Loss Rate} = (\text{Mixing Latent Loss Rate during on cycle} * \text{Run time fraction}) + \text{Mixing Latent Loss Rate during off cycle} * (1.0 - \text{Run time fraction})$$

AirflowNetwork Mixing Latent Loss [J]

The total convective latent heat loss, in Joules, to the zone air corresponding to the Zone Mixing Volume summed over the reporting period.

When a Fan:OnOff object is used, the reported value is weighted by the system run time fraction using the calculated mixing latent loss during the on and off cycles for the reporting period:

$$\text{Mixing Latent Loss} = (\text{Mixing Latent Loss during on cycle} * \text{Run time fraction}) + \text{Mixing Latent Loss during off cycle} * (1.0 - \text{Run time fraction})$$

AirflowNetwork Duct Leak Sensible Gain Rate [W]

This is the average sensible heat gain rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system. This value is averaged over the reporting period. A sensible heat gain occurs when duct air is warmer than zone air. It should be pointed out that when multiple supply air leaks are present in a single zone, the output value is the summation of all the supply air leak gains in this zone. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Sensible Gain [J]

This is the total sensible heat gain, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Sensible Loss Rate [W]

This is the average sensible heat loss rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system. This value is averaged over the reporting period. A sensible heat loss occurs when duct air is cooler than zone air. It should be pointed out that when multiple supply air leaks are present in this zone, the output value is the summation of all the supply air leak losses in this zone. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Sensible Loss [J]

This is the total sensible heat loss, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Gain Rate [W]

This is the average latent heat gain rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system for the reported time period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Gain [J]

This is the total latent heat gain, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Loss Rate [W]

This is the average latent heat loss rate, in Watts, to a specific zone due to supply air leaks from the forced air distribution system for the reported time period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Leak Latent Loss [J]

This is the total latent heat loss, in Joules, to a specific zone due to supply air leaks summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Gain Rate [W]

This is the average sensible heat gain rate, in Watts, of duct conduction to a specific zone where the ducts are located. This value is averaged over the reporting period. A sensible heat gain occurs when duct air is warmer than the zone air. It should be pointed out that when ducts are located in different zones, the total duct conduction loss should be the summation of the duct conduction losses in these zones. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Gain [J]

This is the total sensible heat gain, in Joules, to a specific zone due to duct conduction summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Loss Rate [W]

This is the average sensible heat loss rate, in Watts, of duct conduction to a specific zone where the ducts are located. This value is averaged over the reporting period. A sensible

heat loss occurs when duct air is cooler than the zone air. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Conduction Sensible Loss [J]

This is the total sensible heat loss, in Joules, to a specific zone due to duct conduction summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Gain Rate [W]

This is the average latent heat gain rate, in Watts, of vapor diffusion through the walls of the air distribution system to a specific zone where the ducts are located. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Gain [J]

This is the total latent heat gain, in Joules, to a specific zone due to duct vapor diffusion summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Loss Rate [W]

This is the average latent heat loss rate, in Watts, of duct vapor diffusion to a specific zone where the ducts are located. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Duct Diffusion Latent Loss [J]

This is the total latent heat loss, in Joules, to a specific zone due to duct vapor diffusion summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Gain Rate [W]

This is the average total sensible heat gain rate, in Watts, in a specific zone caused by the forced air distribution system. The total sensible gain rate is the sum of duct leakage sensible gain rate and duct conduction sensible gain rate. This value is averaged over the reporting period. The multizone airflow sensible gain rate is excluded in this output variable. The output of multizone airflow sensible gain is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Gain Rate and AirflowNetwork Mixing Sensible Gain Rate. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Gain [J]

This is the total sensible heat gain, in Joules, in a specific zone caused by the forced air distribution system. The total sensible gain is the sum of duct leakage sensible gain and duct conduction sensible gain. This value is summed over the reporting period. The multizone airflow sensible gain is excluded in this output variable. The output of multizone airflow sensible gain is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Gain and AirflowNetwork Mixing Sensible Gain. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Loss Rate [W]

This is the average total sensible heat loss rate, in Watts, in a specific zone caused by the forced air distribution system. The total sensible loss rate is the sum of duct leakage sensible loss rate and duct conduction sensible loss rate. This value is averaged over the reporting period. The multizone airflow sensible loss rate is excluded in this output variable. The output of multizone airflow sensible loss rate is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Loss Rate and AirflowNetwork Mixing Sensible Loss Rate. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Sensible Loss [J]

This is the total sensible heat loss, in Joules, in a specific zone caused by the forced air distribution system. The total sensible loss is the sum of duct leakage sensible loss and duct conduction sensible loss. This value is summed over the reporting period. The multizone airflow sensible loss is excluded in this output variable. The output of multizone airflow sensible loss is reported in the previously-described output variables AirflowNetwork Infiltration Sensible Loss and AirflowNetwork Mixing Sensible Loss. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Gain Rate [W]

This is the average total latent heat gain rate, in Watts, in a specific zone caused by the forced air distribution system. The total latent gain rate is the sum of duct leakage latent gain rate and duct conduction latent gain rate. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Gain [J]

This is the total latent heat gain, in Joules, in a specific zone caused by the forced air distribution system. The total latent gain is the sum of duct leakage latent gain and duct diffusion latent gain. This value is summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Loss Rate [W]

This is the average total latent heat loss rate, in Watts, in a specific zone caused by the forced air distribution system. The total latent loss rate is a sum of duct leakage latent loss rate and duct diffusion latent loss rate. This value is averaged over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Distribution Latent Loss [J]

This is the total latent heat loss, in Joules, in a specific zone caused by the forced air distribution system. The total latent loss is the sum of duct leakage latent loss and duct diffusion latent loss. This value is summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

NOTE: The following output variables should not be confused with similar output variables for the infiltration, mixing, and cross mixing objects (Ref. Infiltration Output, Mixing Output, or Cross Mixing Output). The output variables described below refer to infiltration, mixing, and cross-mixing when an Airflow Network Simulation is performed. The following output variables are always used to describe infiltration, mixing, and cross mixing when the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to "MultizoneWithoutDistribution" or "MultizoneWithDistribution". In this case the output variables for the infiltration, mixing, and cross mixing objects will always be 0.

In contrast, the following output variables are only used to describe infiltration, mixing, and cross mixing when the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to "MultizoneAirflowWithDistributionOnlyDuringFanOperation" and the fan is operating. When the fan is not operating, the output variables for the infiltration, mixing, and cross mixing objects are used.

In the case where the AirflowNetwork Control field in the AirflowNetwork:SimulationControl object is set to "NoMultizoneOrDistribution", the following output variables are not used and the output variables for the infiltration, mixing, and cross mixing objects are used instead.

AirflowNetwork Infiltration Sensible Gain [J]

The total convective sensible heat gain, in Joules, to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period. This value is calculated for each timestep when the outdoor dry-bulb temperature is higher than the zone temperature, otherwise the sensible gain is set to 0. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Infiltration Sensible Loss [J]

The total convective sensible heat loss, in Joules to the zone air corresponding to the Zone Infiltration Volume summed over the reporting period. When a Fan:OnOff object is used, the reported value is for the system on cycle.

AirflowNetwork Zone Infiltration Volume [m3]

The volume of outdoor air flow into the zone from window/door openings and cracks in the exterior surfaces of the zone (i.e., the sum of ventilation and crack flows from the exterior into the zone). The zone air density is used to calculate the zone infiltration volume based on the mass flow rate. Note that AirflowNetwork Zone Infiltration Volume will be zero if all of the flows through the zone's exterior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration volume calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Infiltration Mass [kg]

The mass of air corresponding to the AirflowNetwork Zone Infiltration Volume. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration mass calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Infiltration Air Change Rate [ach]

The number of air changes per hour produced by outdoor air flow into the zone from window/door openings and cracks in the exterior surfaces of the zone (i.e. the sum of ventilation and crack flows from the exterior into the zone). The target zone air density is used to calculate the zone infiltration air change rate based on the mass flow rate. Note that, like Zone Infiltration Volume, Zone Infiltration Air Change Rate will be zero if all flows through the zone's exterior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the infiltration air change rate calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Mixing Volume [m3]

This is a measure of interzone air flow for each thermal zone. It is the volume of air flow into the zone from adjacent zones through window/door openings and cracks in the interior heat transfer surfaces of the zone. The target zone air density is used to calculate the zone mixing volume based on the mass flow rate. This variable does not include flows that are from the zone to adjacent zones. Note that Zone Mixing Volume will be zero if all flows through the zone's interior surfaces are out of the zone. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing volume calculated during the fan on and off periods for the simulation timestep.

AirflowNetwork Zone Mixing Mass [kg]

The mass of air corresponding to the AirflowNetwork Zone Mixing Volume. When a Fan:OnOff object is used, the reported value is weighted by the system fan part-load ratio using the mixing mass calculated during the fan on and off periods for the simulation timestep.

Group – Zone Equipment

There are five main zone equipment statements that must be used to describe a block of zone equipment as shown in the below figure “Zone Equipment Input Syntax Map”.

Types of Zone equipment are listed below and shown below in figure “Zone Equipment”.

Table 26. Available Zone Equipment Types

Air Distribution Equipment	AirTerminal:SingleDuct:Uncontrolled AirTerminal:SingleDuct:ConstantVolume:Reheat AirTerminal:SingleDuct:VAV:Reheat AirTerminal:SingleDuct:VAV:NoReheat AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan AirTerminal:DualDuct:ConstantVolume AirTerminal:DualDuct:VAV Powered Induction Units (Series and Parallel)
Zone Forced Air Units	ZoneHVAC:IdealLoadsAirSystem ZoneHVAC:FourPipeFanCoil ZoneHVAC:WindowAirConditioner ZoneHVAC:RefrigerationChillerSet Unit Ventilator/Heater Air-to-Air Heat Pumps Unitary Systems (heat only and heat/cool) Furnaces (heat only and heat/cool) Energy Recovery Ventilator:Stand Alone CoilSystem:Cooling:DX
Radiative/Convective Units	Baseboard Heaters Low Temp Radiant Systems High Temp Radiant System

Figure 88. Zone Equipment Input Syntax Map

Figure 89. Representative Zone Equipment

The following figure (Air Loop/Zone Equipment Node Diagram) illustrates the connection between the zone equipment and the air loop systems.

Figure 90. Air Loop/Zone Equipment Node Diagram

Each zone served by an HVAC system must have three additional statements to complete the zone equipment specification. An `ZoneHVAC:AirDistributionUnit` allows equipment

typically found within the zone inlet ductwork (such as dampers, reheat coils, etc.) to be attached to the supply air stream for a particular zone. A ZoneControl statement will allow the conditions in the zone to be managed. Finally, a ZoneHVAC:EquipmentConnections statement describes all of the pertinent information about the zone from an HVAC perspective. Each of these statements is described in more detail below.

ZoneHVAC:AirDistributionUnit

The ZoneHVAC:AirDistributionUnit object gives further information on what air loop equipment (air terminal units) will be serving a particular zone. The ZoneHVAC:AirDistributionUnit is the part of the system that is supplied from a common main air handler simulated in the Air Loop Simulation and includes the equipment that controls or tempers the air going to each individual zone according to the desired thermostatic control. The current options for ZoneHVAC:AirDistributionUnit terminal unit types are:

```
AirTerminal:DualDuct:ConstantVolume
AirTerminal:DualDuct:VAV
AirTerminal:DualDuct:VAV:OutdoorAir
AirTerminal:SingleDuct:ConstantVolume:Reheat
AirTerminal:SingleDuct:VAV:Reheat
AirTerminal:SingleDuct:VAV:NoReheat
AirTerminal:SingleDuct:SeriesPIU:Reheat
AirTerminal:SingleDuct:ParallelPIU:Reheat
AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction
AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan
AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat
AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat
```

Connections between the air distribution unit, the supply air duct, and the zone are specified in the input syntax for the air distribution unit and the AirLoopHVAC:ZoneSplitter. The input syntax also explicitly defines an outlet identifier. This implies a connection to a zone through a NodeList for zone inlets (see the ZoneHVAC:EquipmentConnections statement). The air distribution unit is limited to one combined component-controller unit; because controls are normally based on the zone thermostat and can work in parallel or series in complex fashion. Since the control and the flow resolution can be complex, each air distribution unit is unique in addressing these combinations and therefore only one is allowed per zone.

The Air Distribution unit also allows the user to specify leaks in the supply air duct system. These inputs are used in the EnergyPlus Simplified Duct Leakage Model (SDLM). This model simulates a specific configuration: supply leaks to a return plenum in a commercial VAV or CV system. The system must have a constant static pressure setpoint. Within these limitations SDLM allows the user to easily evaluate the energy penalty due to duct leakage.

Field: Name

Unique identifying name of the air distribution unit.

Field: Air Distribution Unit Outlet Node Name

Outlet node name for the air distribution unit to the attached zone.

Field: Air Terminal Object Type

Single combined component/controller unit for that attached zone. Selection of components as listed above.

Field: Air Terminal Name

The unique identifying component name.

Field: Nominal Upstream Leakage Fraction

This is the leakage upstream of the terminal unit as a fraction of the design flow rate through the unit. It is the leakage fraction at the design flow rate. It is used to calculate a leakage flow

rate which is then held constant while the system air flow varies. This input is optional; the default is zero.

Field: Constant Downstream Leakage Fraction

This is the leakage downstream of the terminal unit as a fraction of the current flow rate through the terminal unit. This fraction is held constant, so the leakage flow rate will vary proportionally with the supply air flow rate. This input is optional; the default is zero.

Two example IDF excerpts (one with duct leakage, one without):

```
ZoneHVAC:AirDistributionUnit,
    SPACE1-1 ATU,          !- Air Distribution Unit Name
    SPACE1-1 In Node,      !- Air Dist Unit Outlet Node Name
    AIRTERMINAL:SINGLEDUCT:VAV:REHEAT, !- KEY--System Component Type 1
    SPACE1-1 VAV Reheat;   !- Component Name 1

ZoneHVAC:AirDistributionUnit,
    SPACE4-1 ATU,          !- Air Distribution Unit Name
    SPACE4-1 In Node,      !- Air Dist Unit Outlet Node Name
    AIRTERMINAL:SINGLEDUCT:VAV:REHEAT, !- KEY--System Component Type 1
    SPACE4-1 VAV Reheat,   !- Component Name 1
    0.05,                  !- upstream nominal leakage fraction
    0.07;                  !- downstream constant leakage fraction
```

ZoneHVAC:EquipmentConnections

Finally, the ZoneHVAC:EquipmentConnections statement defines the remaining details about each thermal zone from an HVAC perspective (besides the controls which were defined above). As with other statements, the first two items in this object are the keyword and an identifying name which links the zone back to its geometrical input, internal gains, etc. and other statements in the HVAC section of the input. The next three items are names of lists (equipment, air inlet nodes, and air exhaust nodes) that are described in more detail below. Note that if there are no air exhaust nodes from the zone that field is left blank. And if there are no air inlet nodes, that field is left blank. Finally, two node names are necessary to complete the zone-HVAC description. The first node is the main air node for the zone upon which the air heat balance is performed. The other node begins the return air path from the zone.

Note that all nodes mentioned in the ZoneHVAC:EquipmentConnections input must be unique. That is, all nodes in all the ZoneHVAC:EquipmentConnections statements referenced by the "Zone Air Inlet Nodes", "Zone Air Exhaust Nodes", "Zone Air Node Name" and "Zone Return Air Node Name" cannot have any node name appearing more than once.

Field: Zone Name

Name links this equipment list back to the heat balance for the zone.

Field: Zone Conditioning Equipment List Name

List of zone equipment for this zone in a ZoneHVAC:EquipmentList object. This list will consist of air distribution units or other direct convection or radiant equipment, i.e. window air conditioner, baseboard, fan coils, etc.

Field: Zone Air Inlet Node or NodeList Name

There can be more than one air inlet node depending on how many pieces of equipment are in the ZoneHVAC:EquipmentList. Generally there will be one air inlet node for each piece of zone equipment that delivers conditioned air to the zone. Components such as electric or hot water baseboards and radiant systems do not require zone air inlet nodes. If there is only one node – its name can be put in this field. If there is more than one node, this must be the name

of a node list object (a node list object can also contain only one node name). If this field is not required (as in the baseboard system), it should be blank.

Field: Zone Air Exhaust Node or NodeList Name

List of exhaust nodes leaving the zone for exhaust fans, zone energy recovery, etc. However these nodes are also used as sources of zone air for zone components such as fan coil units, unit heaters and ventilators, and window air conditioners. For each such component attached to a zone there should be a unique zone exhaust node acting as the inlet node to the component. If there is only one node – its name can be put in this field. If there is more than one node, this must be the name of a node list object (a node list object can also contain only one node name). If there are no air exhaust nodes, this field should be blank.

Field: Zone Air Node Name

The conditions at this node represent the average state of the air in the zone. For zones modeled as fully mixed the conditions at this node are assumed to represent the air in the entire zone. This field is required for all ZoneHVAC:EquipmentConnections statements.

Field: Zone Return Air Node Name

The name of the return air node which attaches the zone to the return air path described above. Even if there is no return air or no return air path a unique name must be entered in this field. The conditions at this node represent the state of the air leaving the zone including any heat gain from light-heat-to-return.

An example of this statement in an IDF is:

```
ZoneHVAC:EquipmentConnections,
  SPACE3-1,          !- Zone Name
  SPACE3-1 Eq,        !- List Name: Zone Equipment
  SPACE3-1 In Nodes,  !- List Name: Zone Air Inlet Nodes
  ,                  !- List Name: Zone Air Exhaust Nodes
  SPACE3-1 Node,      !- Zone Air Node Name
  SPACE3-1 Out Node; !- Zone Return Air Node Name
```

ZoneHVAC:EquipmentList

The first list encountered in the ZoneHVAC:EquipmentConnections statement is the ZoneHVAC:EquipmentList. This object lists all HVAC equipment serving the zone. Each item in the list has four fields associated with it: Object Type, Name, Cooling Sequence and Heating or No-Load Sequence. The Object Type and Name identify the specific equipment object. Cooling Sequence and Heating or No-Load Sequence specify the order of simulation for zones with more than one type of HVAC equipment.

Note that a ZoneHVAC:AirDistributionUnit or AirTerminal:SingleDuct:Uncontrolled must be listed in this statement if there is a forced air system serving the zone from an air loop.

Field: Name

Unique identifying name.

Field Set (Zone Equipment: Object Type, Name, Cooling Sequence, Heating or No-Load Sequence)

This set is used together in order to sequence the equipment for heating and cooling. The #1 sequence equipment will try to meet the entire demand with its capacity and then pass the results on to the #2 and so on for both heating and cooling. This field set is extensible by duplicating the last four fields.

Equipment is simulated in the order specified by Zone Equipment Cooling Sequence and Zone Equipment Heating or No-Load Sequence, depending on the current thermostat request. For equipment of similar type, assign sequence 1 to the first system intended to serve that type of load, assign sequence 2 to the next system, and so on. For situations where one or more equipment types has limited capacity or limited control capability, order

the sequence so that the most controllable piece of equipment runs last. For example, with a dedicated outdoor air system (DOAS), the air terminal for the DOAS should be assigned Heating Sequence = 1 and Cooling Sequence = 1. Any other equipment should be assigned sequence 2 or higher so that it will see the net load after the DOAS air is added to the zone.

Field: Zone Equipment <x> Object Type

Type of zone equipment such as air distribution unit, baseboard, window air conditioner, etc. The current legal types are listed in the following table:

Table 27. Legal Zone Equipment Types (ZoneHVAC:EquipmentList)

Legal Zone Equipment Types
AirTerminal:SingleDuct:Uncontrolled

ZoneHVAC:UnitVentilator
ZoneHVAC:WindowAirConditioner
ZoneHVAC:WaterToAirHeatPump
ZoneHVAC:VentilatedSlab

Field: Zone Equipment <x> Name

Name of the zone equipment used in the object definition of its type.

Field: Zone Equipment <x> Cooling Sequence

Specifies the zone equipment simulation order when the zone thermostat requests cooling.

Field: Zone Equipment <x> Heating or No-Load Sequence

Specifies the zone equipment simulation order when the zone thermostat requests heating or no load.

Examples of this statement in an IDF are:

```

ZoneHVAC:EquipmentList,
Zone1Equipment,           !- Name
ZoneHVAC:AirDistributionUnit,   !- Zone Equipment 1 Object Type
Zone1TermReheat,           !- Zone Equipment 1 Name

2,                         !- Zone Equipment 2 Cooling Sequence
2;                        !- Zone Equipment 2 Heating or No-Load Sequence

```

Group – Air Distribution Equipment

The systems described in the Air Distribution Units (ADU's) are shown below. A variety of air terminal units are available for connecting air systems to thermal zones. These single description ADU's contain the reference to the components and the actual controls in one block of input. The idea is that the control volume is drawn tightly around the controls and loosely around the components. This allows complex interactions to take place between all of the components that respond to the Zone Thermostatic Control output. The coils that are referenced in the ADU's are explained fully in the "Coils" section of this manual.

AirTerminal:SingleDuct:Uncontrolled

Central system air is usually supplied to a zone through a terminal unit such as a single duct VAV reheat box. Sometimes, however, it is desirable to supply central system air directly to a zone without any zone level control or tempering. An example would be a single zone reheat system.

The control zone receives supply air directly from the central system since the supply air temperature has been adjusted to control the temperature in the control zone. The slave zones then have baseboards or reheat coils to allow some temperature adjustment. The AirTerminal:SingleDuct:Uncontrolled object creates the capability of supplying central system air directly to a zone. Its input consists of the object name, an availability (on/off) schedule, and a node name. This node is both a zone inlet node and an outlet node of the AirLoopHVAC:ZoneSplitter.

For the objects to work correctly, it is important in any systems including Direct Air objects for the sum of the maximum zone air flow rates to be equal to the maximum central system flow rate. The zone maximum flow rates are specified in the zone terminal unit or direct air inputs. The central air system flow rate is specified in the AirLoopHVAC input and also in the air loop branch and central fan inputs.

Field: Name

A unique user assigned name for each AirTerminal:SingleDuct:Uncontrolled component. Any other component that needs to use this direct air component will refer to it by this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the component can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the

direct air component can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the direct air component must be off for the hour

Field: Zone Supply Air Node Name

The name of the node to which the direct air component is supplying air. This should be one of the supply air nodes for the zone the direct air component is serving. This node should also be an outlet node of a AirLoopHVAC:ZoneSplitter component.

Field: Maximum Air Flow Rate

The design maximum volume flow rate (m^3/sec) specified for the AirTerminal:SingleDuct:Uncontrolled object. This field is autosizable.

An example input follows.

```
AirTerminal:SingleDuct:Uncontrolled,
  Zone1DirectAir,
  FanAndCoilAvailSched,
  Zone 1 Inlet Node,
  0.47;
AirTerminal:SingleDuct:Uncontrolled,
  Zone2DirectAir,
  FanAndCoilAvailSched,
  Zone 2 Inlet Node,
  0.36;
AirTerminal:SingleDuct:Uncontrolled,
  Zone3DirectAir,
  FanAndCoilAvailSched,
  Zone 3 Inlet Node,
  0.47;
```

AirTerminal:SingleDuct:Uncontrolled Outputs

HVAC , Sum, Direct Air Sensible Heating Energy [J]
HVAC , Sum, Direct Air Sensible Cooling Energy [J]
HVAC , Average, Direct Air Sensible Heating Rate [W]
HVAC , Average, Direct Air Sensible Cooling Rate [W]

Direct Air Sensible Heating Energy [J]

Direct Air Sensible Heating Rate [W]

These outputs are the sensible heating power and energy provided to the zone by the uncontrolled air terminal unit.

Direct Air Sensible Cooling Energy [J]

Direct Air Sensible Cooling Rate [W]

These outputs are the sensible cooling power and energy provided to the zone by the uncontrolled air terminal unit.

AirTerminal:SingleDuct:ConstantVolume:Reheat

The AirTerminal:SingleDuct:ConstantVolume:Reheat system is a constant volume reheat system. The systems cooling capabilities are provided by way of cooling coil that supplies cooling to the entire supply air volume. The cooling coil is controlled by a controller setpoint specified for the cooling coil. Zone control is accomplished by heating (reheating) the airflow into each zone as determined by the zone thermostat. Currently the reheat can be supplied by a electric, gas, or hot water coil that tries to meet the zone demand.

Field: Name

Unique name for the terminal reheat Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The outlet node from the ADU to the zone. This is the same node as the reheat component air outlet node.

Field: Air Inlet Node Name

The air-inlet node name that connects the air splitter to the individual zone ADU. This is the same node as the reheat component air inlet node.

Field: Maximum Air Flow Rate

The design constant volume flow rate (m^3/sec) specified for the terminal reheat ADU.

Control Fields:

The last several fields for this object describe the type of reheat coil that is being used and how it is controlled. Most of the fields pertain to the hot water coil since the gas and electric coil are much more simplified.

Field: Hot Water or Steam Inlet Node Name

For the hot water reheat coil there is a node on the water side that would control the flow to the coil capacity to allow the coil to meet the zone demand. This control location is the name of the control node for the terminal reheat ADU. For the gas and electric coil this is left blank.

Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

```
Coil:Heating:Water  
Coil:Heating:Electric  
Coil:Heating:Gas  
Coil:Heating:Steam
```

Field: Reheat Coil Name

Reheat Coil Object name being simulated with this ADU. Applicable for all coils.

Field: Maximum Hot Water or Steam Flow Rate

This field is 0 for gas and electric coils. Set to the maximum design water flow (m^3/sec) for the hot water coil

Field: Minimum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the minimum design water flow (m^3/sec) for the hot water coil, normally set to be a shut off valve that is set to zero.

Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved for by iteration. The iterative solution uses an interval halving routine and needs a termination criteria that is set with the Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand as the criteria, i.e. 0.001. The default for the field is 0.001.

Field: Maximum Reheat Air Temperature

This is the upper limit on the temperature in degrees C of the air leaving the terminal unit – reheat coil (and being delivered to the zone). If the user leaves this field blank, no maximum reheat air temperature is enforced.

An IDF example:

```
AirTerminal:SingleDuct:ConstantVolume:Reheat,
  Reheat Zone 1, !- Name of System
  FanAndCoilAvailSched, !- Availability schedule for VAV System
  Zone 1 Reheat Air Outlet Node, !- Unit Air Outlet Node
  Zone 1 Reheat Air Inlet Node, !- Unit Air Inlet Node
  0.59, !- Maximum air flow rate {m3/s}
  , !- Control node
  COIL:Gas:Heating, !- Reheat Component Object
  Reheat Coil Zone 1, !- Name of Reheat Component
  0.0, !- Max Reheat Water Flow {m3/s}
  0.0, !- Min Reheat Water Flow {m3/s}
  0.001; !- Convergence Tolerance
```

AirTerminal:SingleDuct:ConstantVolume:Reheat Outputs

There are no outputs for the constant volume reheat air terminal.

AirTerminal:SingleDuct:VAV:Reheat

AirTerminal:SingleDuct:VAV:Reheat - Variable air volume (VAV) systems control the dry-bulb temperature inside a zone by varying the supply air volume instead of the air temperature. At full cooling the VAV damper is fully open supplying the specified maximum air flow rate. As the cooling load decreases, the damper closes until it reaches the minimum stop specified by the zone minimum air flow fraction.

VAV systems can be used for interior or perimeter zones with a common fan system, air temperature control, and reheating devices. The VAV concept may vary according to the VAV box locations, air temperature controls and types of heating elements. Heating can usually be provided by use of reheat coils or thermostatic baseboard.

Field: Name

Unique name for the AirTerminal:SingleDuct:VAV:Reheat Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Damper Air Outlet Node Name

The VAV damper outlet node. This is the outlet node of the damper and the inlet node of the reheat coil.

Field: Air Inlet Node Name

The air inlet node name that connects the air splitter to the individual zone ADU. This is *not* the same as the air inlet node of the reheat component: it is upstream of that node. This is the inlet node to the terminal unit and the damper

Field: Maximum Air Flow Rate

The design maximum volume flow rate (m^3/sec) specified for VAV ADU.

Field: Zone Minimum Air Flow Method

This field is used to select how the program will determine the minimum flow rate to the zone while the system is operating. There are three choices for selecting how the minimum flow rate is specified: Constant, FixedFlowRate, and Scheduled. If Constant is entered, then the program will use the value for the constant minimum air flow fraction entered in the following field. If FixedFlowRate is entered, then the program will use the value entered in the field

below called Fixed Minimum Air Flow Rate. If Scheduled is entered, then the program will obtain the value for minimum flow fraction from the schedule named in the field below called Minimum Air Flow Fraction Schedule Name.

Field: Constant Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Constant. If the previous field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils. If this field and the following field have values, the greater of the two is used for sizing.

Field: Fixed Minimum Air Flow Rate

The minimum flow rate to the zone while the system is operating, specified as a fixed minimum air flow rate in meters cubed per second. The minimum air flow rate is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the Zone Minimum Air Flow Method field is set to FixedFlowRate. If the Zone Minimum Air Flow Method field is set to Scheduled (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then this field is optional and can be used to separately control the air flow rate used for sizing normal-action reheat coils. Only one of these two minimum air flow fields (i.e., this field and the previous field) should be used at any time. If this field and the previous field have values, the greater of the two is used for sizing.

Field: Minimum Air Flow Fraction Schedule Name

The name of a schedule that determines the value of the minimum air flow fraction. The schedule should contain fractions from 0.0 to 1.0. These values will define the minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The reheat coil operates only when the damper is at this minimum flow rate when Damper Heating Action is set to Normal (the default). This field is used if the previous field is set to Scheduled. If the previous field is left blank (and the field Maximum Hot Water or Steam Flow Rate is set to autosize), then the air flow rate used for sizing normal-action reheat coils is the average of the minimum and maximum values in this schedule. The air flow rate used for reheat coil sizing is reported with other component sizing information as "Reheat Coil Sizing Air Volume Flow Rate."

Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam

If there is no reheat coil, use AirTerminal:SingleDuct:VAV:NoReheat instead of this object.

Field: Reheat Coil Name

Reheat Coil Object name being simulated with this ADU. Applicable for all coils. If there is no reheat coil, use object AirTerminal:SingleDuct:VAV:NoReheat instead of this object.

Field: Maximum Hot Water or Steam Flow Rate

This field is 0 for gas and electric coils. Set to the maximum design water flow (m^3/sec) for the hot water coil. This field is autosizable. If there is no reheat coil, this is left blank.

Field: Minimum Hot Water or Steam Flow Rate

This field is zero for gas and electric coils. Set to the minimum design water flow (m^3/sec) for the hot water coil, normally set to be a shut off valve that is set to zero. If there is no reheat coil, this is left blank.

Field: Air Outlet Node Name

The terminal unit outlet node. This is the outlet node of the reheat coil and the zone inlet node.

Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved for by iteration. The iterative solution uses an interval halving routine and needs a termination criteria that is set with the Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand as the criteria, i.e. 0.001. The default for the field is 0.001.

Field: Damper Heating Action

During heating operation, there are two control options for the damper controlling the air flow in the VAV terminal unit as the zone moves above or below the zone setpoint. With both control options, the damper is at the minimum air flow rate whenever the zone temperature is between the cooling and heating setpoints (deadband condition).

With **Normal** (the default) action, the damper will remain at the minimum air flow rate during heating operation. As the heating load increases, the water flow rate in the reheat coil will be increased to maintain temperature in the zone until the maximum water flow rate is reached or the user-specified maximum reheat air temperature is reached.. This is sometimes called the single maximum control logic as illustrated below.

Figure 91. The Single Maximum Control Logic

With **Reverse** action, as the heating load increases, the unit starts at minimum air flow and minimum hot water flow. The hot water flow is increased until it reaches maximum flow or the user-specified maximum reheat air temperature is reached, then the air damper starts to

open to meet the load. This option is used if the minimum air flow rate is not adequate to serve the peak heating load. This is sometimes called the dual maximum control logic as illustrated in following figure. For heating coil types other than the hot-water coil, e.g. electric, steam, and gas, the reverse action works the same as the normal action – always keeping the air flow at the minimum during heating.

The dual-max control currently applies to the AirTerminal:SingleDuct:VAV:Reheat objects with reverse acting dampers and hot-water coils.

Figure 92. The Dual Maximum Control Logic

Control Fields for Maximum Flow During Reheat:

The following two fields are used only when Reheat Coil Object Type = Coil:Heating:Water and Damper Heating Action = Reverse. Maximum Flow per Zone Floor Area During Reheat and Maximum Flow Fraction During Reheat are two optional methods to calculate the maximum allowable air flow rate during reheat operation. If both are entered, the greater resulting flow rate is used. If Design Specification Outdoor Air Object Name is also specified, it may increase this limit to meet the outdoor air flow rate requirement. At no time will the maximum flow rate calculated here exceed the value for Maximum Air Flow Rate.

This limit is active only when the zone thermostat requests heating and the VAV box damper is reverse acting.

Field: Maximum Flow per Zone Floor Area During Reheat

This factor ($\text{m}^3/\text{s}\cdot\text{m}^2$) is multiplied by the zone area, to determine the maximum volume flow rate (m^3/s) allowed during reheat operation (see detailed explanation above). This field is autocalculatable. If autocalculate is selected, the value is set to $0.002032 \text{ m}^3/\text{s}\cdot\text{m}^2$ ($0.4 \text{ cfm}/\text{ft}^2$). If this field and the following field are entered, the greater of the two inputs is used. If this field and the following field are left blank, the maximum flow will not be limited.

Field: Maximum Flow Fraction During Reheat

This fraction is multiplied by the Maximum Air Flow Rate to determine the maximum volume flow rate (m^3/s) allowed during reheat operation (see detailed explanation above). This field is autocalculatable. If autocalculate is selected, the value is set to $0.002032 \text{ m}^3/\text{s}\cdot\text{m}^2$ ($0.4 \text{ cfm}/\text{ft}^2$) multiplied by the zone floor area divided by the Maximum Air Flow Rate. If this field and the previous field are entered, the greater of the two inputs is used. If this field and the previous field are left blank, the maximum flow will not be limited.

Field: Maximum Reheat Air Temperature

This field specifies a maximum supply air temperature (°C) leaving the reheat coil in a VAV terminal unit during heating operation. If leaving blank, the temperature of the supply air to the space in heating operation may get unrealistic high.

Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a DesignSpecification:OutdoorAir object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person is non-zero, then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref DesignSpecification:OutdoorAir).

AirTerminal:SingleDuct:VAV:Reheat Outputs

HVAC,Average,VAV Terminal Damper Position []

HVAC,Average,VAV Terminal Minimum Air Flow Fraction []
HVAC,Average,VAV Terminal Outdoor Air Flow Rate [m ³ /s]

VAV Terminal Damper Position

This output is the variable air volume damper position required to meet the zone load. This is the average value over the frequency being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

VAV Terminal Minimum Air Flow Fraction

This output is the value for the minimum air flow fraction setting on a VAV terminal. This is the average value over the frequency being reported. The minimum air flow fraction is defined as the lower limit on the terminal unit air mass flow rate divided by the terminal units maximum air mass flow rate.

VAV Terminal Outdoor Air Flow Rate

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan

The VAV terminal unit with variable-speed fan and reheat coil is an air system terminal unit consisting of a variable speed fan in series with a heating coil. These units are usually employed in underfloor air distribution (UFAD) systems where the air is supplied at low static pressure through an underfloor plenum. The fan is used to control the flow of conditioned air that enters the space. When the fan is off the plenum pressure drives the minimum air flow through the terminal unit. At maximum cooling the fan runs at its maximum speed. At full heating the fan runs at its heating maximum – usually less than the cooling maximum flow rate. Thus this unit has two separate maximum flow rates – one for heating and one for cooling.

For cooling, control is maintained simply by varying the fan speed. For heating, the unit first tries to meet the heating load by varying the heating coil output while keeping the air flow at minimum (fan off). If this is not adequate the fan turns on and operates in variable flow mode up to the heating maximum flow rate.

This unit is modeled in EnergyPlus as a compound component – a variable speed fan and a heating coil in series in the air stream. The unit is blow through – the fan is upstream of the heating coil.

Field: Name

A unique user assigned name for a particular VS fan VAV reheat terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Cooling Air Flow Rate

The maximum volumetric air flow rate through the unit in cubic meters per second when the thermostat is calling for cooling. Normally this is the same as the unit's fan maximum volumetric flow rate.

Field: Maximum Heating Air Flow Rate

The maximum volumetric air flow rate through the unit in cubic meters per second when the thermostat is calling for heating.

Field: Zone Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. For this unit this is the flow rate when the fan is off.

Field: Air Inlet Node Name

The name of the HVAC system node that is the air inlet node for the terminal unit. This is also the air inlet node for the unit's fan.

Field: Air Outlet Node Name

The name of the HVAC system node that is the air outlet node of the unit. This same node will be the unit heating coil's air outlet node. This node is also a zone inlet node.

Field: Heating Coil Air Inlet Node Name

The name of the HVAC system node that is the air inlet node of the unit's heating coil. The same node is the outlet node of the unit's fan. This is an internal node of this compound component.

Field: Hot Water or Steam Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit's hot water heating coil. This should be the same node as the water inlet node of the hot water coil. For gas or electric coils this field should be left blank.

Field: Fan Object Type

The type of fan in the terminal unit. At this time the only type of fan allowed is *Fan:VariableVolume*.

Field: Fan Name

The name of the particular fan object in this terminal unit.

Field: Heating Coil Object Type

The type of heating coil in the terminal unit. The valid choices are:

Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam

Field: Heating Coil Name

The name of the heating coil object contained in this terminal unit.

Field: Maximum Hot Water or Steam Flow Rate

The maximum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is not a hot water coil this field should be left blank.

Field: Minimum Hot Water or Steam Flow Rate

The minimum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is not a hot water coil this field should be left blank.

Field: Heating Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified

output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone load}|}{Q_{zone load}} \leq ConvergenceTolerance$$

The default is 0.001.

AirTerminal:SingleDuct:VAV:Reheat:VariableSpeedFan Outputs

HVAC,Average,VAV Terminal Flow Fraction []

VAV Terminal Flow Fraction

This output is the variable air volume flow fraction required to meet the zone load. This is the average value over the frequency being reported. The flow fraction is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat

Variable air volume (VAV) systems typically control the dry-bulb temperature inside a zone by varying the supply air volume instead of the supply air temperature (ref: AirTerminal:SingleDuct:VAV:NoReheat). Reheat coils may be required to avoid overcooling (ref: AirTerminal:SingleDuct:VAV:Reheat).

This terminal unit is slightly different from the AirTerminal:SingleDuct:VAV:Reheat terminal unit. Both operate the same in cooling mode: the damper opens as needed to provide additional sensible cooling to the zone. The difference between the two is in heating mode. For the Single Duct VAV Reheat terminal unit, the air flow rate is reduced to the minimum value (max air flow rate x zone minimum air flow fraction) when zone heating is required and the reheat coil output is modulated to meet the zone heating load. For the AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat terminal unit, the air flow rate in heating mode is increased to meet higher zone heating loads (similar to what is done in cooling mode). If additional heat is required (beyond what the terminal unit can provide with its damper fully open), then the reheat coil is modulated as needed to meet the additional heating load.

This terminal unit model was originally developed and tested for use with the changeover-bypass VAV unitary system.

Figure 93. Single Duct VAV Heat and Cool Reheat Schematic

Field: Name

Unique user-defined name for this Air Distribution Unit (ADU).

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether or not this component is available to operate during a given time period. If a schedule value is greater than zero then the system is available to operate; otherwise, the system is unavailable for that time period.

Field: Damper Air Outlet Node Name

This alpha field defines the name of the VAV damper air outlet node. This is the outlet node of the damper and the inlet node of the reheat coil.

Field: Air Inlet Node Name

This alpha field defines the name of the air inlet node that connects the air splitter to the individual zone ADU. This is *not* the same as the air inlet node of the reheat component: it is upstream of that node. This is the inlet node to the terminal unit and the damper.

Field: Maximum Air Flow Rate

This numeric field defines the design maximum volumetric flow rate (m^3/sec) specified for this VAV ADU. This flow rate must be greater than 0 or can be autosized.

Field: Zone Minimum Air Flow Fraction

This numeric field defines the minimum air volumetric flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. The reheat coil operates as needed to maintain the heating set point specified in the Zone Control:Thermostatic object. This value must be between 0 and 1.

Control Fields:

The last several fields for this terminal reheat component describe the type of reheat coil that is being used and how it is controlled. Most of the fields pertain to the hot water coil since the gas and electric coil are much more simplified.

Field: Hot Water or Steam Inlet Node Name

For the hot water reheat coil there is a node on the water side that would control the water flow rate to allow the coil to meet the zone demand. This control location is the name of the control node for this terminal reheat ADU. For the gas and electric coils this field is left blank.

Field: Reheat Coil Object Type

The valid reheat component objects currently available are:

```
Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam
```

If no reheat coil is required, use AirTerminal:SingleDuct:VAV:HeatAndCool>NoReheat instead of this object.

Field: Reheat Coil Name

Unique coil name being simulated with this ADU. Applicable for all coils. If there is no reheat coil, use AirTerminal:SingleDuct:VAV:HeatAndCool>NoReheat instead of this object.

Field: Maximum Hot Water or Steam Flow Rate

This field is ignored for gas or electric reheat coils. If using a hot water or steam reheat coil, set to the maximum design water or steam volumetric flow rate (m^3/sec) for the hot water or steam coil. This flow rate can be autosized.

Field: Minimum Hot Water or Steam Flow Rate

This field is ignored for gas and electric coils. Set to the minimum design water volumetric flow rate (m^3/sec) for the hot water or steam coil, normally set to be a shut-off valve that is set to zero.

Field: Air Outlet Node Name

This is the air outlet node for the ADU and is then connected to the zone. This is the same node as the air outlet node of the reheat component.

Field: Convergence Tolerance

The coil is controlled by knowing the zone demand determined by the zone thermostat and setting the outlet conditions to meet this demand. For the electric and gas coils, this is set exactly since the coil model solution can be inverted and this field is not used. With the hot water coil that uses an effectiveness-NTU method, the solution cannot be inverted directly. Therefore, to determine the correct mass flow rate for the hot water the solution is solved by iteration. The iterative solution uses an interval-halving routine and needs a termination criteria that is set with this Convergence Tolerance parameter. This control offset is set to a decimal fraction of the zone demand. The default value for this field is 0.001.

Field: Maximum Reheat Air Temperature

This is the upper limit on the temperature in degrees C of the air leaving the terminal unit – reheat coil (and being delivered to the zone). If the user leaves this field blank, no maximum reheat air temperature is enforced.

An IDF example is provided below:

AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat Outputs

HVAC,Average,VAV Terminal Damper Position []
--

VAV Terminal Damper Position

This output is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

AirTerminal:SingleDuct:VAV:NoReheat

Variable air volume (VAV) systems control the dry-bulb temperature inside a zone by varying the supply air volume instead of the air temperature. At full cooling the VAV damper is fully open supplying the specified maximum air flow rate. As the cooling load decreases, the damper closes until it reaches the minimum stop specified by the zone minimum air flow fraction.

VAV systems can be used for interior or perimeter zones with a common fan system and air temperature control. The VAV concept may vary according to the VAV box locations and air temperature controls. Heating can be provided if necessary by use of baseboard.

Field: Name

Unique name for the VAV Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The VAV damper and Unit outlet node.

Field: Air Inlet Node Name

The air inlet node name that connects the air splitter to the individual zone ADU.

Field: Maximum Air Flow Rate

The design maximum volume flow rate (m^3/sec) specified for VAV ADU. This is autosizable.

Field: Zone Minimum Air Flow Method

This field is used to select how the program will determine the minimum flow rate to the zone while the system is operating. The minimum flow rate is modeled as a fraction of the maximum flow rate. There are five choices: Constant, FixedFlowRate, Scheduled, Sum and Maximum. If Constant is entered, then the program will use the value for minimum flow fraction entered in the following field. If FixedFlowRate is entered, then the program will use the value for minimum flow rate entered in the field below called Fixed Minimum Air Flow Rate. If Scheduled is entered, then the program will obtain the value for minimum flow fraction from the schedule named in the field below called Minimum Air Flow Fraction Schedule Name. Sum and Maximum are used to either provide the summation of all "entered" inputs or the maximum of all "entered" inputs.

Field: Constant Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. This field is only used if the Zone Minimum Air Flow Method field is set to Constant.

Field: Fixed Minimum Air Flow Rate

The minimum flow rate to the zone while the system is operating, specified as a fixed minimum air flow rate in meters cubed per second. The minimum air flow rate is normally specified to meet the minimum ventilation requirement for the occupants. This field is only used if the Zone Minimum Air Flow Method field is set to FixedFlowRate.

Field: Minimum Air Flow Fraction Schedule Name

The name of a schedule that determines the value of the minimum air flow fraction. The schedule should contain fractions from 0.0 to 1.0. These values will define the minimum flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. This field is only used if the Zone Minimum Air Flow Method field is set to Scheduled.

Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a DesignSpecification:OutdoorAir object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person is non-zero, then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref DesignSpecification:OutdoorAir).

AirTerminal:SingleDuct:VAV:NoReheat Outputs

HVAC,Average,VAV Terminal Damper Position []
HVAC,Average,VAV Terminal Outdoor Air Flow Rate [m3/s]

VAV Terminal Damper Position

This output is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

VAV Terminal Outdoor Air Flow Rate

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outside air system.

AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat

Variable air volume (VAV) systems typically control the dry-bulb temperature inside a zone by varying the supply air volume instead of the supply air temperature (ref: AirTerminal:SingleDuct:VAV:NoReheat). Reheat coils may be required to avoid overcooling (ref: AirTerminal:SingleDuct:VAV:Reheat).

This terminal unit is slightly different from the AirTerminal:SingleDuct:VAV:NoReheat terminal unit. Both operate the same in cooling mode: the damper opens as needed to provide additional sensible cooling to the zone. The difference between the two is in heating mode. For the Single Duct VAV NoReheat terminal unit, the air flow rate is reduced to the minimum value (max air flow rate x zone minimum air flow fraction) when zone heating is required. For the AirTerminal:SingleDuct:VAV:HeatAndCool:NoReheat terminal unit, the air flow rate in heating mode is increased to meet higher zone heating loads (similar to what is done in cooling mode).

This terminal unit model was originally developed and tested for use with the changeover-bypass VAV unitary system..This object may be used when the central heating coil is sufficient to maintain the heating set point temperature. Additional heating may be provided, if necessary, by use of AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat or ZoneHVAC:Baseboard:* objects.

Figure 94. Single Duct VAV Heat and Cool NoReheat Schematic

Field: Name

Unique user-defined name for this Air Distribution Unit (ADU).

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether or not this component is available to operate during a given time period. If a schedule value is greater than zero then the system is available to operate; otherwise, the system is unavailable for that time period.

Field: Air Outlet Node Name

This alpha field defines the name of the VAV damper air outlet node.

Field: Air Inlet Node Name

This alpha field defines the name of the air inlet node that connects the air splitter to the individual zone ADU.

Field: Maximum Air Flow Rate

This numeric field defines the design maximum volume flow rate (m^3/sec) specified for this VAV ADU. This flow rate must be greater than 0 or can be autosized.

Field: Zone Minimum Air Flow Fraction

This numeric field defines the minimum air volume flow rate to the zone while the system is operating, specified as a fraction of the maximum air flow rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants. This value must be between 0 and 1.

An IDF example is provided below:

```

VAV Terminal Damper Position

This output is the damper position required to meet the zone load. This is the average value over the simulation timestep being reported. The damper position is defined as the terminal unit air mass flow rate divided by the terminal unit's maximum air mass flow rate.

AirTerminal:SingleDuct:SeriesPIU:Reheat

The series powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a fixed flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The fan runs at a constant volume flow rate whenever the unit is on (and the fan's availability schedule is on or it is activated by an availability manager). The fan is downstream of the primary and secondary air inlets. The variable mixing is accomplished by a damper in the unit's primary air supply inlet duct. This damper can move from fully open (100% primary air, 0% secondary air) to a minimum stop that is specified in the input description. At full cooling and for heating the damper will be fully open. At minimum cooling and for heating the damper will be at the minimum stop and the secondary air flow will be at its maximum.

The EnergyPlus model of the series PIU terminal unit is composed of three components: a zone mixer, a constant volume fan, and a heating coil (hot water, electric, or gas).

Figure 95. Series PIU Terminal Unit

Field: Name

A unique user assigned name for a particular series powered induction terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Air Flow Rate

The maximum volumetric air flow rate through the unit in cubic meters per second. Since this is a constant air volume unit, this is also the design, rated air flow rate of the unit.

Field: Maximum Primary Air Flow Rate

The maximum volumetric air flow rate of primary air through the unit in cubic meters per second. This is the primary air flow rate at full cooling load when the primary air damper is fully open. Usually this quantity is the same as the total unit flow rate, but it can be less.

Field: Minimum Primary Air Flow Fraction

The minimum volumetric air flow rate of primary air through the unit expressed as a fraction of the maximum volumetric air flow rate of primary air. This input can be 0.0.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

Field: Secondary Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air. The unit can draw secondary air from its conditioned zone directly or from a return air plenum. Thus this node should be one of the zones exhaust air nodes (see *Zone Air Exhaust Node* in **ZoneHVAC:EquipmentConnections**) or an induced air node outlet of a return plenum (see *Induced Air Outlet Node* in **AirLoopHVAC:ReturnPlenum**).

Field: Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Reheat Coil Air Inlet Node Name

The name of the HVAC system node which is the inlet node of the unit's heating coil. This is also the outlet node of the unit's fan.

Field: Zone Mixer Name

The name of an zone mixer component (object: **AirLoopHVAC:ZoneMixer**) which composes part of the unit. Note that some of the input for the mixer will duplicate input fields of the powered induction unit. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the PIU; the other inlet node of the zone mixer should be the same as the secondary air inlet node of the PIU. The outlet node of the zone mixer should be the same as the inlet node of the PIU fan.

Field: Fan Name

The name of a fan component which composes part of the unit. Note that the fan's maximum flow rate should be the same as the maximum air flow rate of the PIU and the type of fan object must be **Fan:ConstantVolume**. The fan's inlet node should be the same as the zone mixer's outlet node. The fan's outlet node should be the same as the heating coil's air inlet node. The secondary fan will run according to the Availability Schedule specified in the **Fan:ConstantVolume** object, unless it is overridden by an availability manager (ref. **AvailabilityManager:NightCycle** and others).

Field: Reheat Coil Object Type

The type of coil in the PIU. The valid choices are:

Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam

In other words the PIU may have a hot water, gas, electric or steam reheat coil.

Field: Reheat Coil Name

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the fan outlet node and the heating coil's air outlet node is the same as the PIU outlet node.

Field: Maximum Hot Water or Steam Flow Rate

The maximum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

Field: Minimum Hot Water or Steam Flow Rate

The minimum hot water volumetric flow rate in m³/sec through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

Field: Hot Water or Steam Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit. This should be the same node as the water inlet node of the unit's hot water coil. For gas or electric heating coils, this input should be blank.

Field: Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{PIU,out} - Q_{zone load}|}{Q_{zone load}} \leq ConvergenceTolerance$$

For gas or electric heating coils, this input should be left blank. The default is 0.001.

An IDF example:

AirTerminal:SingleDuct:SeriesPIU:Reheat Outputs

HVAC,Average,PIU Heating Rate[W]
HVAC,Sum,PIU Heating Energy[J]
HVAC,Average,PIU Sensible Cooling Rate[W]
HVAC,Sum,PIU Sensible Cooling Energy[J]

PIU Heating Rate[W]

This field reports the dry air heating addition rate of the series PIU terminal unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the terminal unit.

PIU Heating Energy[J]

This field reports the dry air heat addition of the series PIU terminal unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

PIU Sensible Cooling Rate[W]

This field reports the dry air sensible heat extraction rate of the series PIU terminal unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the terminal unit.

PIU Sensible Cooling Energy[J]

This field reports the dry air sensible heat extraction of the series PIU terminal unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

AirTerminal:SingleDuct:ParallelPIU:Reheat

The parallel powered induction unit is an air system terminal unit that mixes varying amounts of secondary (recirculated) air and primary (conditioned supply) air to produce a variable total flow of air to a zone. The unit contains a small fan that acts to induce the secondary air and a heating coil for heating the mixed secondary and primary air. The secondary and primary air streams enter the unit in parallel. The fan sits in the secondary air stream and runs only when the primary air flow is below the Fan On Flow Fraction and the fan's availability schedule is on or it is activated by an availability manager. The primary air inlet contains a damper that can move from fully open (maximum primary air) to a minimum stop (minimum primary air).

At full cooling load the primary air damper is fully open and the fan is off. The primary air flow is at maximum and there is little or no secondary air flow. As the cooling load decreases, the primary air damper gradually closes and the secondary air flow remains close to zero. At some point, usually when the primary air flow has reached the minimum, the fan switches on and secondary air is induced. The heating coil will switch on as needed to meet any heating demand.

The EnergyPlus model of the parallel PIU terminal unit is composed of three components: a constant volume fan, a zone mixer, and a heating coil (hot water, electric, or gas).

Figure 96. Parallel PIU Terminal Unit

Field: Name

A unique user assigned name for a particular parallel powered induction terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Primary Air Flow Rate

The maximum volumetric air flow rate of primary air through the unit in cubic meters per second. This is the primary air flow rate at full cooling load when the primary air damper is fully open.

Field: Maximum Secondary Air Flow Rate

The maximum volumetric air flow rate of secondary air through the unit in cubic meters per second. This flow rate can be any amount but is commonly less than the maximum primary air flow rate.

Field: Minimum Primary Air Flow Fraction

The minimum volumetric air flow rate of primary air through the unit expressed as a fraction of the maximum volumetric air flow rate of primary air. This input can be 0.0.

Field: Fan On Flow Fraction

The fraction of the primary air flow at which fan turns on. In the parallel PIU the fan operation is intermittent. If the primary air flow is above this fraction of the maximum, the fan is off. Otherwise the secondary fan will run according to the Availability Schedule specified in the Fan:ConstantVolume object (see Fan Name below), unless it is overridden by an availability manager (ref. AvailabilityManager:NightCycle and others).

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

Field: Secondary Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air. The unit can draw secondary air from its conditioned zone directly or from a return air plenum. Thus this node should be one of the zones exhaust air nodes (see Zone Air Exhaust

Node in **ZoneHVAC:EquipmentConnections**) or an induced air node outlet of a return plenum (see *Induced Air Outlet Node* in **AirLoopHVAC:ReturnPlenum**).

Field: Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Reheat Coil Air Inlet Node Name

The name of the HVAC system node which is the inlet node of the unit's heating coil. This is also the outlet node of the unit's zone mixer.

Field: Zone Mixer Name

The name of an zone mixer component (object: **AirLoopHVAC:ZoneMixer**) which composes part of the unit. Note that some of the input for the mixer will duplicate input fields of the powered induction unit. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the PIU; the other inlet node of the zone mixer should be the same as the air outlet node of the fan. The outlet node of the zone mixer should be the same as the inlet node of the heating coil.

Field: Fan Name

The name of a fan component which composes part of the unit. Note that the fan's maximum flow rate should be the same as the maximum secondary air flow rate of the PIU and the type of fan object must be **Fan:ConstantVolume**. The fan's inlet node should be the same as the PIU secondary air inlet node. The fan's outlet node should be the same as one of the zone mixer's inlet nodes. When the primary air flow is below the Fan On Flow Fraction (above), the secondary fan will run according to the Availability Schedule specified in the **Fan:ConstantVolume** object, unless it is overridden by an availability manager (ref. **AvailabilityManager:NightCycle** and others).

Field: Reheat Coil Object Type

The type of coil in the PIU. The valid choices are:

Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam

In other words the PIU may have a hot water, gas, electric or steam reheat coil.

Field: Reheat Coil Name

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the zone mixer's outlet node and the heating coil's air outlet node is the same as the PIU outlet node.

Field: Maximum Hot Water or Steam Flow Rate

The maximum hot water volumetric flow rate in m^3/sec through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

Field: Minimum Hot Water or Steam Flow Rate

The minimum hot water volumetric flow rate in m^3/sec through the unit's heating coil. If the heating coil is gas or electric this field should be blank.

Field: Hot Water or Steam Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit. This should be the same node as the water inlet node of the unit's hot water coil. For gas or electric heating coils, this input should be blank.

Field: Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{PIU,out} - Q_{zone load}|}{Q_{zone load}} \leq ConvergenceTolerance$$

For gas or electric heating coils, this input should be left blank. The default is 0.001.

AirTerminal:SingleDuct:ParallelPIU:Reheat Outputs

HVAC,Average,PIU Heating Rate[W]
HVAC,Sum,PIU Heating Energy[J]
HVAC,Average,PIU Sensible Cooling Rate[W]
HVAC,Sum,PIU Sensible Cooling Energy[J]

PIU Heating Rate[W]

This field reports the dry air heating addition rate of the parallel PIU terminal unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the terminal unit.

PIU Heating Energy[J]

This field reports the dry air heat addition of the parallel PIU terminal unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

PIU Sensible Cooling Rate[W]

This field reports the sensible heat extraction rate of the parallel PIU terminal unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the terminal unit.

PIU Sensible Cooling Energy[J]

This field reports the dry air sensible heat extraction of the parallel PIU terminal unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the terminal unit, and the timestep.

AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction

The four pipe induction terminal unit provides local hot water heating or chilled water cooling of induced zone air which then mixes with centrally conditioned supply air. An air conditioning system consisting of these terminal units is effectively a mixed central air / local hydronic system. The centrally conditioned air supplied to the induction terminal units is constant volume at quite high pressure. The central air is discharged through a nozzle in the terminal unit, inducing a flow of room air over a hydronic heating/cooling coil. The coil is connected either to a single inlet and outlet pipe (2 pipe unit) or to 2 inlets and 2 outlets (4 pipe unit). The heated or cooled induced air mixes with the centrally conditioned air before being discharged into the zone. The terminal units are usually expected to do only sensible cooling – any dehumidification is done by the central air conditioning system.

The EnergyPlus model of the four pipe induction terminal unit is a compound component consisting of a hot water heating coil, a chilled water cooling coil, and an air mixer. The unit has two inlet air streams: the centrally conditioned supply air and the induced air from the zone. The induced air passes first through the heating coil, then through the cooling coil and finally through the mixer. The central supply air goes directly into the mixer. The water flow through the hot or cold water coil is varied to meet the zone air conditioning requirement. Note that EnergyPlus models the four pipe induction terminal unit as having separate heating and cooling coils whereas real units have only a single coil used for both heating and cooling. Note also that the four pipe induction unit model can be used to model a two pipe unit by simply adjusting the heating and cooling coil schedules so that the heating coil is off when the cooling coil is on and vice versa.

Field: Name

A unique user assigned name for a particular four pipe induction terminal unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Maximum Total Air Flow Rate

The maximum volumetric air flow rate discharged from the unit in cubic meters per second. Since this is a constant air volume unit, this is also the design, rated air flow rate of the unit. Note that this is the total discharge flow rate – including both central supply and induced air.

Field: Induction Ratio

The ratio of induced air flow rate to primary supply air flow rate. The default is 1.0 –the supply air induces an equal amount of zone air.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air

Field: Induced Air Inlet Node Name

The name of the HVAC system node from which the unit draws its secondary or recirculated air. This should be the same node as one of the zone exhaust nodes.

Field: Air Outlet Node Name

The name of the HVAC system node to which the unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Hot Water Inlet Node Name

The name of the HVAC system node which regulates the flow of hot water through the unit. This should be the same node as the water inlet node of the unit's hot water coil.

Field: Cold Water Inlet Node Name

The name of the HVAC system node which regulates the flow of cold water through the unit. This should be the same node as the water inlet node of the unit's chilled water coil.

Field: Heating Coil Object Type

The type of heating coil in the terminal unit. The choices are:

Coil:Heating:Water

In other words the unit may have a hot water coil only.

Field: Heating Coil Name

The name of the heating coil component which composes part of the unit. Note that the heating coil's air inlet node is the same as the terminal unit's induced air inlet node. The heating coil's air outlet node is the same as the cooling coil's air inlet node.

Field: Maximum Hot Water Flow Rate

The maximum hot water volumetric flow rate in m³/sec through the unit's heating coil.

Field: Minimum Hot Water Flow Rate

The minimum hot water volumetric flow rate in m³/sec through the unit's heating coil.

Field: Heating Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone load}|}{Q_{zone load}} \leq ConvergenceTolerance$$

The default is 0.001.

Field: Cooling Coil Object Type

The type of cooling coil in the terminal unit. The choices are:

Coil:Cooling:Water

Coil:Cooling:Water:DetailedGeometry

In other words the unit must use only the water cooling coils.

Field: Cooling Coil Name

The name of the cooling coil component which composes part of the unit. Note that the cooling coil's air inlet node is the same as the heating coil's air outlet node. The cooling coil's air outlet node is the same as one of the zone mixer's inlets.

Field: Maximum Cold Water Flow Rate

The maximum cold water volumetric flow rate in m³/sec through the unit's cooling coil.

Field: Minimum Cold Water Flow Rate

The minimum cold water volumetric flow rate in m³/sec through the unit's cooling coil.

Field: Cooling Convergence Tolerance

The control tolerance for the unit cooling output. The unit is controlled by matching the unit output to the zone demand. The model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{unit,out} - Q_{zone\ load}|}{Q_{zone\ load}} \leq ConvergenceTolerance$$

The default is 0.001.

Field: Zone Mixer Name

The name of an zone mixer component (object: AirLoopHVAC:ZoneMixer) which composes part of the terminal unit. Note that some of the zone mixer's inputs will duplicate some of the terminal units's inputs. One of the zone mixer inlet nodes should be the same as the supply air inlet node of the terminal unit; the other inlet node of the zone mixer should be the same as the cooling coil air outlet node. The outlet node of the zone mixer should be the same as the outlet node of the terminal unit.

An IDF example:

AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction Outputs

There are no specific outputs for the four pipe induction terminal units.

AirTerminal:SingleDuct:ConstantVolume:CooledBeam

The Cooled Beam system is a mixed air-hydraulic system. A central, single-duct forced-air system supplies conditioned ventilation air to the zones. Sensible cooling is done by chilled water circulating through ceiling mounted cooled beam units. Chilled water flow rate through the cooled beam units is varied to meet the zone sensible cooling load. Any dehumidification is done by the central ventilation air system. Heating is usually accomplished with hot water radiators. Thermodynamically, the cooled beam system resembles the four-pipe induction unit.

To model a typical cooled beam system the user will need to define a conventional central constant volume forced air system. This system will normally be 100% outside air delivered at a fixed supply temperature (which could be reset by schedule or by outside air temperature). On the supply side of this air loop there will be the usual central AC equipment: outside air mixer, fan, heating and cooling coil. On the zone equipment (demand) side of the loop, the chilled beams will be represented as terminal units. Additional zone equipment (such as baseboard heaters) will be needed to handle heating loads.

Although the cooled beam equipment in a zone is treated by the program as a single terminal unit, the actual installation will have multiple beams in each zone. The program (in its sizing calculation for the system) figures out how many beams of what length are needed to meet the zone design load.

Field: Name

A unique user assigned name for a particular chilled beam unit. Any reference to this unit by another object will use this name.

Field: Unit Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be

on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Cooled Beam Type

Two types of units are modeled: *Active* or *Passive*. In the active unit, primary air is supplied through the beam, inducing some secondary zone air into contact with the coil. This unit acts as an active convector. The passive unit is simply a passive, finned convector. Primary air is supplied through a normal diffuser.

Field: Supply Air Inlet Node Name

The name of the HVAC system node from which the unit draws its primary or supply air. Note that this field should be specified for both types of unit, even though supply air does not pass through the passive unit.

Field: Supply Air Outlet Node Name

The name of the air node that connects this terminal unit to the zone. The will be the same as one of the zone inlet nodes. The name of this node must be entered even if the actual beams are passive and is not actually supplying air to the zone.

Field: Chilled Water Inlet Node Name

The name of the chilled water inlet node.

Field: Chilled Water Outlet Node Name

The name of the chilled water outlet node.

Field: Supply Air Volumetric Flow Rate

This is the air flow rate in cubic meters per second of the supply air entering the zone. This input would normally be autosized based on the ventilation requirement (see Zone Sizing).

Field: Maximum Total Chilled Water Volumetric Flow Rate

The maximum chilled water flow rate (in cubic meters per second) for the unit. This input would normally be autosized based on the zone design load.

Field: Number of Beams

The number of individual cooled beam units in the zone. Normally this unit would be autocalculated by the program based upon the previous field and the nominal flow rate for a single beam unit (set by the program to 0.07 kg/s).

Field: Beam Length

The length of an individual beam in meters. Normally this will be autocalculated by the program based upon the number of beam units and the zone design sensible cooling load. 1 to 4 meters is a typical length range.

Field: Design Inlet Water Temperature

The nominal or design inlet water temperature in degrees Celsius. The default is 15C.

Field: Design Outlet Water Temperature

The nominal or design outlet water temperature in degrees Celsius. The default is 17C.

The following inputs are parameters used to characterize the performance of the chilled beam units. Values for a given unit can be obtained from the manufacturer. The parameters are used in the following equations.

$$P_{beam} = A \cdot K \cdot \Delta T$$

beam cooling output per unit length W/m

$$K = \alpha \cdot \Delta T^{n1} \cdot v \rho^{n2} \cdot \omega^{n3}$$

coil heat transfer coefficient W/(m²K)

$$\nu \rho = (q_{in}/\alpha_0) \cdot \rho_{air}$$

room air mass flow rate across coil kg/(m²s)

$$q_{in} = K_1 \cdot \Delta T^n + K_{in} \cdot q_{pr}$$

room air volumetric flow rate across coil per
unit length $\text{m}^3/(\text{s}\cdot\text{m})$

ΔT is the room air –water temperature difference (average water temperature is used) in degrees C.

ω is the water velocity in m/s.

q_{pr} is the supply air flow rate per unit length $\text{m}^3/(\text{s}\cdot\text{m})$

Field: Coil Surface Area per Coil Length

Surface area on the air side of the beam per unit beam length. The units are square meters per meter. The default is 5.422. This is A in the above equations.

Field: Model Parameter α (a)

This is α in the above equations. The default is 15.3

Field: Model Parameter n1

This is $n1$ in the above equations. The default is 0.

Field: Model Parameter n2

This is $n2$ in the above equations. The default is 0.84.

Field: Model Parameter n3

This is $n3$ in the above equations. The default is 0.12.

Field: Model Parameter α_0 (a)

This is α_0 in the above equations. It is the free area of the coil in plan view (for the air flow) per unit beam length. The units are square meters per meter. The default is 0.171.

Field: Model Parameter K_1 (K1)

This is K_1 in the above equations. The default is 0.005.

Field: Model Parameter n

This is n in the above equations. The default is 0.4.

Field: Coefficient of Induction K_{in} (Kin)

The coefficient of induction K_{in} in the above equations. The default is 2.0 for active beams and 0.0 for passive beams.

Field: Pipe Inside Diameter

The water pipe inside diameter in meters. The default is 0.0145.

An example input is:

Heating by the supply air to the zone, exclusive of any cooling done by the beams.

AirTerminal:DualDuct:ConstantVolume

The AirTerminal:DualDuct:ConstantVolume simulation or the typical Multizone is described by this Air Distribution Unit (ADU). Multizone systems condition all the air in a central apparatus and distribute it to the conditioned zones through two parallel ducts. One duct carries cold air and the other warm air, providing air sources for both heating and cooling at all times. In each conditioned zone, a mixing valve responsive to a room thermostat mixes the warm and cold air in proper proportions to satisfy the prevailing heating or cooling load of the space. The Multizone ADU is the specific component that leads to the zone containing the mixer and the mixing damper and then connecting to the zone. The total airflow to each room is kept constant while the proportion of hot air to cold air is adjusted to maintain the temperature in each zone at the desired level.

Field: Name

Unique name for the Multizone ADU.

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The outlet node from the ADU to the zone.

Field: Hot Air Inlet Node Name

The air-inlet node name that connects the hot air splitter to the individual zone ADU.

Field: Cold Air Inlet Node Name

The air-inlet node name that connects the cold air splitter to the individual zone ADU.

Field: Maximum Air Flow Rate

The design constant volume flow rate (m³/sec) specified for that Multizone ADU.

AirTerminal:DualDuct:ConstantVolume Outputs

HVAC,Average,Dual Duct Terminal Cold Air Damper Position []
HVAC,Average,Dual Duct Terminal Hot Air Damper Position []

Dual Duct Terminal Cold Air Damper Position

This output is the damper position of the cold air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit cold air mass flow rate divided by the terminal unit's maximum cold air mass flow rate.

Dual Duct Terminal Hot Air Damper Position

This output is the damper position of the hot air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit hot air mass flow rate divided by the terminal unit's maximum hot air mass flow rate.

AirTerminal:DualDuct:VAV

AirTerminal:DualDuct:VAV (i.e., Dual duct variable air volume (DDVAV)) systems are used to obtain zone temperature control by mixing the cold and warm air in various volume combinations. The fan is sized for the anticipated maximum coincident hot or cold volume, not the sum of the instantaneous peaks. This system has an advantage of a true single path VAV system, except for warm port leakage. When cold air is modulated for control before mixing, it operates similar to the VAV induction when mixing occurs without hot deck reheat. It is similar to a reheat system when mixing occurs while the hot deck is using the reheat coil. It uses more energy than a true VAV system, but less than a constant volume dual duct system.

Field: Name

Unique name for the AirTerminal:DualDuct:VAV Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The outlet node from the ADU to the zone.

Field: Hot Air Inlet Node Name

The air-inlet node name that connects the hot air splitter to the individual zone ADU.

Field: Cold Air Inlet Node Name

The air-inlet node name that connects the cold air splitter to the individual zone ADU.

Field: Maximum Damper Air Flow Rate

The design maximum volume flow rate (m³/sec) specified for DDVAV ADU.

Field: Zone Minimum Air Flow Fraction

The minimum flow rate to the zone while the system is operating, specified as a fraction of the Max Damper Air Flow Rate. The minimum zone fraction is normally specified to meet the minimum ventilation requirement for the occupants.

Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a DesignSpecification:OutdoorAir object. When this field is used, the terminal unit will increase flow as needed to meet this outdoor air requirement. If Outdoor Air Flow per Person is non-zero, then the outdoor air requirement will be computed based on the current number of occupants in the zone. At no time will the supply air flow rate exceed the value for Maximum Air Flow Rate. If this field is blank, then the terminal unit will not be controlled for outdoor air flow. See documentation for the zone HVAC outdoor air object for further information (Ref DesignSpecification:OutdoorAir).

AirTerminal:DualDuct:VAV Outputs

HVAC,Average,Dual Duct Terminal Cold Air Damper Position []
HVAC,Average,Dual Duct Terminal Hot Air Damper Position []

HVAC,Average,VAV Terminal Outdoor Air Flow Rate [m ³ /s]

Dual Duct Terminal Cold Air Damper Position

This output is the damper position of the cold air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit cold air mass flow rate divided by the terminal unit's maximum cold air mass flow rate.

Dual Duct Terminal Hot Air Damper Position

This output is the damper position of the hot air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit hot air mass flow rate divided by the terminal unit's maximum hot air mass flow rate.

VAV Terminal Outdoor Air Flow Rate

This output is the amount of outdoor air entering the zone. This is the average value over the frequency being reported. The amount of outdoor air is defined as the terminal unit air volume flow rate multiplied by the fraction of outdoor air entering the air loop's outdoor air system.

AirTerminal:DualDuct:VAV:OutdoorAir

AirTerminal:DualDuct:VAV:OutdoorAir provides a model for a type of dual duct air system in which one duct provides outdoor air ventilation and the other provides VAV cooling. The Outdoor Air stream and the Recirculated Air stream are conditioned and supplied through separate air streams as part of a centralized dedicated outdoor air (DOAS) distribution system. The dual duct arrangement allows the ventilation air to be controlled separately using schedules or occupancy demand while the recirculated air is controlled to meet the dry-bulb zone temperature setpoint. The two airstreams remain decoupled until the terminal box where they are mixed. The terminal unit is meant for systems regulating outdoor air based only on demand control or code minimum settings and not on economizer operation.

This air terminal does not have heating coils and is not configured for conditions zones that need heat. Additional ZoneHVAC equipment, such as baseboards or fan coil units, are needed to provide heating to the zone when using this air terminal.

Although this air terminal is primarily for dual duct system, it is allowed to use just the outdoor air side in a single duct system. This can be useful for modeling single duct DOAS when the required volume of outdoor air varies over time.

Field: Name

Unique name for the AirTerminal:DualDuct:VAV:OutdoorAir Air Distribution Unit (ADU).

Field: Availability Schedule Name

Schedule that this component will operate or is available to operate.

Field: Air Outlet Node Name

The outlet node of the terminal unit. This is the node leaving the unit and serving as the inlet to the zone. It is for the mixed flow leaving from both of the inlet node.

Field: Outdoor Air Inlet Node Name

The inlet node of the Outdoor Air (OA) stream deck of the Dual Duct system.

Field: Recirculated Air Inlet Node Name

The inlet node of the Recirculated Air (RA) stream deck of the Dual Duct system. This input is optional. If no node name is entered here, then the recirculation duct is disabled and the model functions as a single duct terminal and no second cooling deck is needed.

Field: Maximum Zone Total Airflow Rate

Max total airflow rate (in m³/s) at the terminal unit outlet including both the Outdoor Air stream and the Recirculated stream. Can be autosized based on the Design Outdoor Airflow Rate and the zone thermal cooling load. The autosized flow rate will be the sum of the maximum outdoor air requirement and the flow for cooling. When autosizing, this maximum and the individual inlet flow rate sizes are reported to the eio file.

Field: Design Specification Outdoor Air Object Name

This field specifies the name of a DesignSpecification:OutdoorAir object. This field is required for this object. The terminal unit will modulate the Outdoor Air stream to meet this outdoor air requirement. If Outdoor Air Flow per Person is applied, then the outdoor air required will be based on either the current number of occupants in the zone, as for demand controlled ventilation, or the design level of occupants depending on the setting in the next field.

Field: Per Person Ventilation Rate Mode

This field specifies how the outdoor air ventilation rates are calculated when based on a rate per person. It can be either based on the current number of people as affected by time-varying occupancy schedules, or on the constant value for the maximum number of people. Enter the key CurrentOccupancy for the former and DesignOccupancy for the later.

An example input object follows.

Dual Duct Outdoor Air Terminal Damper Position

This output is the damper position of the outdoor air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit outdoor air mass flow rate divided by the terminal unit's maximum outdoor air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

Dual Duct Recirculated Air Terminal Damper Position

This output is the damper position of the recirculated cool air stream in a dual duct air terminal. This is the average value over the frequency being reported. The damper position is defined as the terminal unit cool air mass flow rate divided by the terminal unit's maximum cool air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

Dual Duct Outdoor Air Fraction

This output is the current fraction of outdoor air contained in the combined flow of air entering the zone from the terminal unit. This is the average value over the frequency being reported. The outdoor air fraction is defined as the terminal unit outdoor air mass flow rate divided by the total air mass flow rate. This output is dimensionless and ranges from 0.0 to 1.0.

Group – Zone Forced Air Units

ZoneHVAC:IdealLoadsAirSystem

The simplest piece of zone equipment is the ZoneHVAC:IdealLoadsAirSystem component. ZoneHVAC:IdealLoadsAirSystem is used in situations where the user wishes to study the performance of a building without modeling a full HVAC system. In such a case, the Ideal Loads Air System is usually the sole conditioning component: the user does not need to specify air loops, water loops, etc. All that is needed for the ideal system are zone controls, zone equipment configurations, and the ideal loads system component.

This component can be operated with infinite or finite heating and cooling capacity. For either mode – infinite or limited capacity – the user can also specify on/off schedules for heating and cooling and outdoor air controls. There are also optional controls for dehumidification, humidification, economizer, and heat recovery. This component may be used in combination with other HVAC equipment serving the same zone.

This component can be thought of as an ideal unit that mixes air at the zone exhaust condition with the specified amount of outdoor air and then adds or removes heat and moisture at 100% efficiency in order to produce a supply air stream at the specified conditions. The energy required to condition the supply air is metered and reported as DistrictHeating and DistrictCooling.

Notes: The ideal loads system uses the zone return node or an optional zone exhaust node to extract air from the zone. Every zone served by an HVAC component must have a return air node, even though this node may not be connected to anything.

The ideal loads system was significantly expanded in version 7.0 (October 2011). As part of this upgrade, any change in the moisture content of the supply air stream results in a latent cooling (dehumidification) or latent heating (humidification) load which is metered as DistrictCooling and DistrictHeating energy consumption. Prior to version 7.0, when the ideal loads system was in heating mode, only the energy for sensible heating was metered. This results in significant changes in reported energy use compared to earlier versions, especially when using the **ConstantSupplyHumidityRatio** option for Humidification Control Type.

Older idf files which are transitioned to version 7.0 will automatically be set to use the **ConstantSupplyHumidityRatio** option for both dehumidification and humidification controls, because this is equivalent to the controls used in the older version of this system. However, the user should review all of the humidity control options and select the one which best reflects the goal of the simulation.

Field: Name

A unique user assigned name for each ideal loads air system component. This name is referenced in a ZoneHVAC:EquipmentList object.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether or not this component is available to operate during a given time period. If the schedule value is greater than zero then the system is available to operate; otherwise, the system is unavailable for that time period. If left blank, the system will always be available.

Field: Zone Supply Air Node Name

The name of the outlet air node of the ideal loads object. This should be the same as one of the zone air inlet nodes for the zone the ideal loads component is serving.

Field: Zone Exhaust Air Node Name

The name of the zone exhaust air node of the ideal loads object. This should be the same as one of the zone air exhaust nodes for the zone this component is serving. This node name is required if ZoneHVAC:IdealLoadsAirSystem is used in a zone which also has other forced air HVAC equipment. Otherwise this node name is optional but recommended.

Field: Maximum Heating Supply Air Temperature

The maximum air temperature (degrees C) of the air used for heating the zone. The default is 50C (122F).

Field: Minimum Cooling Supply Air Temperature

The minimum air temperature (degrees C) of the air used for cooling the zone. The default is 13C (55.4F).

Field: Maximum Heating Supply Air Humidity Ratio

The maximum humidity ratio (kg of water per kg of dry air) of the hot supply air. The default is 0.0156 kg-H₂O/kg-air which corresponds to a 20%RH at 50C (122F) dry bulb.

Field: Minimum Cooling Supply Air Humidity Ratio

The minimum humidity ratio (kg of water per kg of dry air) of the cool supply air. The default is 0.0077 kg-H₂O/kg-air which corresponds to a 10C (50F) dew point.

Field: Heating Limit

The input must be either **LimitFlowRate**, **LimitCapacity**, **LimitFlowRateAndCapacity** or **NoLimit**. **LimitFlowRate** means that the heating supply air flow rate will be limited to the value specified in the next input field. **LimitCapacity** means that the sensible heating capacity will be limited to the value specified in the Maximum Sensible Heating Capacity field. **LimitFlowRateAndCapacity** means that both flow rate and capacity will be limited. **NoLimit** (the default) means that there will not be any limit on the heating supply air flow rate or capacity and the subsequent two fields will be ignored.

Field: Maximum Heating Air Flow Rate

The maximum heating supply air flow rate in cubic meters per second if heating limit is set to **LimitFlowRate** or **LimitFlowRateAndCapacity**. This field may be autosized. This field is ignored if heating limit is set to **NoLimit** or **LimitCapacity**. If blank, there is no limit.

Field: Maximum Sensible Heating Capacity

The maximum allowed sensible heating capacity in Watts if Heating Limit is set to **LimitCapacity** or **LimitFlowRateAndCapacity**. This field may be autosized. If blank, there is no limit. If Heating Limit is set to **NoLimit** or **LimitFlowRate**, this field is ignored.

Field: Cooling Limit

The input must be either **LimitFlowRate**, **LimitCapacity**, **LimitFlowRateAndCapacity** or **NoLimit**. **LimitFlowrate** means that the cooling supply air flow rate will be limited to the

value specified in the next input field. ***LimitCapacity*** means that the total cooling capacity will be limited to the value specified in the Maximum Total Cooling Capacity field. ***LimitFlowRateAndCapacity*** means that both flow rate and capacity will be limited. ***NoLimit*** (the default) means that there will not be any limit on the cooling supply air flow rate or capacity and the subsequent two fields will be ignored.

Field: Maximum Cooling Air Flow Rate

The maximum cooling supply air flow rate in cubic meters per second if Cooling Limit is set to ***LimitFlowRate*** or ***LimitFlowRateAndCapacity***. This field may be autosized. This field is ignored if cooling limit is set to ***NoLimit*** or ***LimitCapacity***. If blank, there is no limit. If Cooling Limit is set to ***NoLimit***, this field is ignored. This field is required if Outdoor Air Control Type is ***TemperatureEconomizer*** in order to establish an upper limit on outdoor air flow when the economizer is active.

Field: Maximum Total Cooling Capacity

The maximum allowed total (sensible plus latent) cooling capacity in Watts if Cooling Limit is set to ***LimitCapacity*** or ***LimitFlowRateAndCapacity***. This field may be autosized. If blank, there is no limit. If Cooling Limit is set to ***NoLimit*** or ***LimitFlowRate***, this field is ignored.

Field: Heating Availability Schedule Name

The name of a schedule (ref: Schedule) that denotes whether heating is available. A schedule value greater than 0 (usually 1 is used) indicates that heating and humidification are available. A value less than or equal to 0 (usually 0 is used) denotes that heating and humidification are not available. If blank, heating and humidification are always available.

Field: Cooling Availability Schedule Name

The name of a schedule (ref: Schedule) that denotes whether cooling is available. A schedule value greater than 0 (usually 1 is used) indicates that cooling and dehumidification are available. A value less than or equal to 0 (usually 0 is used) denotes that cooling and dehumidification is not available. If blank, cooling and dehumidification are always available.

Field: Dehumidification Control Type

Select from ***ConstantSensibleHeatRatio***, ***Humidistat***, ***None***, or ***ConstantSupplyHumidityRatio***. ***ConstantSensibleHeatRatio*** (the default) means that the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using a constant sensible heat ratio (SHR) (see next field). ***Humidistat*** means that there is a ZoneControl:Humidistat for this zone and the ideal loads system will attempt to meet the humidistat request (i.e. will dehumidify according to the Dehumidifying Relative Humidity Schedule in the ZoneControl:Humidistat object). ***None*** means that there is no dehumidification. ***ConstantSupplyHumidityRatio*** means that during cooling the supply air will always be at the Minimum Cooling Supply Humidity Ratio. For ***ConstantSensibleHeatRatio*** and ***Humidistat***, if the mixed air humidity ratio is less than the target humidity ratio, then the mixed air humidity ratio will be used. For all options, the supply air humidity ratio will never be allowed to exceed saturation at the supply dry bulb temperature.

The selected dehumidification control type is always applied when the unit is in cooling mode. If the unit is in deadband mode (not actively heating the supply air) control type ***Humidistat*** will be active. If the unit is in heating mode, control type ***Humidistat*** will be active if the Humidification Control Type field below is set to ***Humidistat*** or ***None***.

This allows the ideal loads system to heat and dehumidify at the same time.

Field: Cooling Sensible Heat Ratio

When the Dehumidification Control Type is set to ***ConstantSensibleHeatRatio*** the ideal loads system will be controlled to meet the sensible cooling load, and the latent cooling rate will be computed using the value of Cooling Sensible Heat Ratio (SHR), where SHR =

Sensible Cooling divided by Total Cooling (sensible plus latent). The default is 0.7. If Dehumidification Control Type is set to something other than **ConstantSensibleHeatRatio** then this field will be ignored.

Field: Humidification Control Type

Select from **None**, **Humidistat**, or **ConstantSupplyHumidityRatio**. **None** means that there is no humidification. **Humidistat** means that there is a ZoneControl:Humidistat for this zone and the ideal loads system will attempt to meet the humidistat request (i.e., humidify according to the Humidifying Relative Humidity Setpoint Schedule in the ZoneControl:Humidistat object). **ConstantSupplyHumidityRatio** means that during heating the supply air will always be at the Maximum Heating Supply Humidity Ratio. The default is **None**. For **Humidistat**, if the mixed air humidity ratio is greater than the target humidity ratio, then the mixed air humidity ratio will be used. For all options, the supply air humidity ratio will never be allowed to exceed saturation at the supply dry bulb temperature.

The selected humidification control type is always applied when the unit is in heating mode. If the unit is in deadband mode (not actively heating the supply air) control type **Humidistat** will be active. If the unit is in cooling mode, control type **Humidistat** will be active if the Dehumidification Control Type field above is set to *Humidistat* or *None*.

This allows the ideal loads system to cool and humidify at the same time.

Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a DesignSpecification:OutdoorAir object which specifies the outdoor air requirements and schedule for this system. The outdoor air flow rate may also be affected by the next two fields, Demand Controlled Ventilation Type and Outdoor Air Economizer Type. If this field is blank, this system will have no outdoor air, and all outdoor air control and heat recovery options will be ignored..

Field: Outdoor Air Inlet Node Name

This alpha field specifies the node name of the outdoor air inlet node. This node name is also specified in an OutdoorAir:Node or OutdoorAir:NodeList object. If this field is blank, a node name will be created internally.

Field: Demand Controlled Ventilation Type

This field, along with the Design Specification Outdoor Air Object (if used) specifies how the minimum outdoor air flow rate is calculated. The choices are: **None**, **OccupancySchedule** or **CO2Setpoint**. The default is **None**.

- **None** means that the design occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field).
- **OccupancySchedule** means that the current occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field).
- **CO2Setpoint** means that the design occupancy level will be used when computing the minimum outdoor air flow rate based on the inputs in the Design Specification Outdoor Air Object (see previous field). In addition, the minimum outdoor air flow rate may be increased if necessary to maintain the level of indoor air carbon dioxide at or below the setpoint defined in a ZoneControl:ContaminantController object.

Field: Outdoor Air Economizer Type

This field specifies if there is an outdoor air economizer. The choices are: **NoEconomizer**, **DifferentialDryBulb**, or **DifferentialEnthalpy**. The default is **NoEconomizer**. **DifferentialDryBulb** and **DifferentialEnthalpy** mean that the economizer will increase the outdoor air flow rate above the minimum outdoor air flow (see fields Design Specification Outdoor Air Object Name and Demand Controlled Ventilation Type) when there is a cooling

load and the outdoor air temperature or enthalpy is below the zone exhaust air temperature or enthalpy. The **DifferentialDryBulb** and **DifferentialEnthalpy** options require that the Maximum Cooling Air Flow Rate be specified which will be used as the limit for maximum outdoor air flow rate.

Field: Heat Recovery Type

Select from **None**, **Sensible**, or **Enthalpy**. **None** means that there is no heat recovery. **Sensible** means that there is sensible heat recovery whenever the zone exhaust air temperature is more favorable than the outdoor air temperature. **Enthalpy** means that there is latent and sensible heat recovery whenever the zone exhaust air enthalpy is more favorable than the outdoor air enthalpy. The default is **None**.

Field: Sensible Heat Recovery Effectiveness

The sensible heat recovery effectiveness, where effectiveness is defined as the change in supply temperature divided by the difference in entering supply and relief air temperatures. The default is 0.70.

Field: Latent Heat Recovery Effectiveness

The latent heat recovery effectiveness, where effectiveness is defined as the change in supply humidity ratio divided by the difference in entering supply and relief air humidity ratios. The default is 0.65.

Ideal Loads Output Variable Overview

All of the ZoneHVAC:IdealLoadsAirSystem loads and energy use are reported for Sensible Heating, Latent Heating, Total Heating, Sensible Cooling, Latent Cooling, and Total Cooling. To explain the relationship between the various outputs, Total Cooling Energy will be used.

Ideal Loads Total Cooling Energy is the district cooling energy consumed by the ideal loads system “cooling coil” to cool and dehumidify the supply air.

Ideal Loads Zone Total Cooling Energy is the total (sensible plus latent) cooling energy delivered to the zone. If there is no outdoor air, then *Ideal Loads Total Cooling Energy* = *Ideal Loads Zone Total Cooling Energy*.

Ideal Loads Outdoor Air Total Cooling Energy is the total (sensible plus latent) cooling energy required to cool the outdoor air to the zone exhaust air temperature and humidity ratio.

Ideal Loads Heat Recovery Total Cooling Energy is the total (sensible plus latent) cooling energy supplied by heat recovery. This offsets a portion of the *Ideal Loads Outdoor Air Total Cooling Energy*.

When the economizer is not active, these values are related by the following equation:

$$\text{Ideal Loads Total Cooling Energy} + \text{Ideal Loads Heat Recovery Total Cooling Energy} = \\ \text{Ideal Loads Zone Total Cooling Energy} + \text{Ideal Loads Outdoor Air Total Cooling Energy}$$

Ideal Loads Sensible Heating Energy [J]

Ideal Loads Sensible Heating Rate [W]

The sensible heating energy (or rate) added to raise the temperature of the mixed air stream to the temperature of the supply air stream. This is the ideal “heating coil” load.

Ideal Loads Latent Heating Energy [J]

Ideal Loads Latent Heating Rate [W]

The latent heating energy (or rate) added to raise the humidity ratio of the mixed air stream to the temperature of the supply air stream. This is the ideal “humidifier” load.

Ideal Loads Total Heating Energy [J]

Ideal Loads Total Heating Rate [W]

The total (sensible and latent) heating energy (or rate) added to raise the mixed air stream to the temperature and humidity ratio of the supply air stream. *Ideal Loads Total Heating Energy* is metered as DistrictHeating energy.

Ideal Loads Sensible Cooling Energy [J]

Ideal Loads Sensible Cooling Rate [W]

The sensible cooling energy (or rate) removed to lower the temperature of the mixed air stream to the temperature of the supply air stream. This is the ideal “cooling coil” sensible load.

Ideal Loads Latent Cooling Energy [J]

Ideal Loads Latent Cooling Rate [W]

The latent cooling energy (or rate) removed to lower the humidity ratio of the mixed air stream to the temperature of the supply air stream. This is the ideal “cooling coil” latent load.

Ideal Loads Total Cooling Energy [J]

Ideal Loads Total Cooling Rate [W]

The total (sensible and latent) cooling energy (or rate) removed to lower the mixed air stream to the temperature and humidity ratio of the supply air stream. *Ideal Loads Total Cooling Energy* is metered as DistrictCooling energy. This is the ideal “cooling coil” total load.

Ideal Loads Zone Sensible Heating Energy [J]

Ideal Loads Zone Sensible Heating Rate [W]

The sensible heating energy (or rate) added to the zone.

Ideal Loads Zone Latent Heating Energy [J]

Ideal Loads Zone Latent Heating Rate [W]

The latent heating energy (or rate) added to the zone.

Ideal Loads Zone Total Heating Energy [J]

Ideal Loads Zone Total Heating Rate [W]

The total (sensible and latent) heating energy (or rate) added to the zone.

Ideal Loads Zone Sensible Cooling Energy [J]***Ideal Loads Zone Sensible Cooling Rate [W]***

The sensible cooling energy (or rate) removed from the zone.

Ideal Loads Zone Latent Cooling Energy [J]***Ideal Loads Zone Latent Cooling Rate [W]***

The latent cooling energy (or rate) removed from the zone.

Ideal Loads Zone Total Cooling Energy [J]***Ideal Loads Zone Total Cooling Rate [W]***

The total (sensible and latent) cooling energy (or rate) removed from the zone.

Ideal Loads Outdoor Air Sensible Heating Energy [J]***Ideal Loads Outdoor Air Sensible Heating Rate [W]***

The sensible heating energy (or rate) required to raise the temperature of the outdoor air to the zone exhaust air temperature. This value will be calculated only when heating is active.

Ideal Loads Outdoor Air Latent Heating Energy [J]***Ideal Loads Outdoor Air Latent Heating Rate [W]***

The latent heating energy (or rate) required to raise the humidity ratio of the outdoor air to the zone exhaust air humidity ratio. This value will be calculated only when humidification is active.

Ideal Loads Outdoor Air Total Heating Energy [J]***Ideal Loads Outdoor Air Total Heating Rate [W]***

The total (sensible and latent) heating energy (or rate) required to raise the temperature and humidity ratio of the outdoor air to the zone exhaust air humidity ratio. This value will be calculated only when heating or humidification is active.

Ideal Loads Outdoor Air Sensible Cooling Energy [J]***Ideal Loads Outdoor Air Sensible Cooling Rate [W]***

The sensible cooling energy (or rate) required to lower (or raise) the temperature of the outdoor air to the zone exhaust air temperature. This value will be calculated only when cooling is active.

Ideal Loads Outdoor Air Latent Cooling Energy [J]***Ideal Loads Outdoor Air Latent Cooling Rate [W]***

The latent cooling energy (or rate) required to lower (or raise) the humidity ratio of the outdoor air to the zone exhaust air humidity ratio. This will be calculated only when dehumidification is active.

Ideal Loads Outdoor Air Total Cooling Energy [J]***Ideal Loads Outdoor Air Total Cooling Rate [W]***

The total (sensible and latent) cooling energy (or rate) required to lower the temperature and humidity ratio of the outdoor air to the zone exhaust air temperature and humidity ratio. This value will be calculated only when cooling or dehumidification is active.

Ideal Loads Heat Recovery Sensible Heating Energy [J]***Ideal Loads Heat Recovery Sensible Heating Rate [W]***

The sensible heating energy (or rate) added to the outdoor air stream from heat recovery.

Ideal Loads Heat Recovery Latent Heating Energy [J]***Ideal Loads Heat Recovery Latent Heating Rate [W]***

The latent heating energy (or rate) added to the outdoor air stream from heat recovery.

Ideal Loads Heat Recovery Total Heating Energy [J]***Ideal Loads Heat Recovery Total Heating Rate [W]***

The total (sensible and latent) heating energy (or rate) added to the outdoor air stream from heat recovery.

Ideal Loads Heat Recovery Sensible Cooling Energy [J]***Ideal Loads Heat Recovery Sensible Cooling Rate [W]***

The sensible cooling energy (or rate) removed from the outdoor air stream from heat recovery.

Ideal Loads Heat Recovery Latent Cooling Energy [J]***Ideal Loads Heat Recovery Latent Cooling Rate [W]***

The latent cooling energy (or rate) removed from the outdoor air stream from heat recovery.

Ideal Loads Heat Recovery Total Cooling Energy [J]***Ideal Loads Heat Recovery Total Cooling Rate [W]***

The total (sensible and latent) cooling energy (or rate) removed from the outdoor air stream from heat recovery.

Ideal Loads Time Economizer Active [hr]

Hours when the Ideal Loads economizer increased the outdoor air flow rate above the minimum.

Ideal Loads Time Heat Recovery Active [hr]

Hours when the Ideal Loads heat recovery was actively heating or cooling the outdoor air stream.

Ideal Loads Hybrid Ventilation Availability Status []

This is the availability status of the ideal loads object as set by the hybrid ventilation manager. Rules to determine the availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 and 1. These integers represent NoAction (0) and ForceOff (1). When the availability status is ForceOff, the unit is turned off regardless of its availability schedule. The other status flag i.e. NoAction does not control the unit and the controls of the unit turn it back on. Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:FourPipeFanCoil

What is a fan coil unit? Like many HVAC terms, “fan coil unit” is used rather loosely. Sometimes it is used for terminal units that would be better described as powered induction units. Carrier and others use the term for the room side of refrigerant-based split systems. Here we are modeling in-room forced-convection hydronic units. Typically these units are

small (200 – 1200 cfm) and self-contained. They are mostly used in exterior zones, usually in hotels, apartments, or offices. They may be connected to ducted outside air, or have a direct outside air vent, but they do not have outside air economizers. Units with outside air economizers are marketed (in the United States) as unit ventilators. Unit ventilators are typically bigger than fan coils and are widely used in classrooms or other applications where ventilation is a priority. If a zonal unit with an outside economizer is desired, *ZoneHVAC:UnitVentilator* should be used.

The heating or cooling output of the unit ventilator is controlled by varying the air flow rate, the water flow rate, or both. Air flow rate can be controlled by cycling the fan on/off or with a variable speed fan drive. The most common setup is a two or three speed fan with the speed selected by hand. The fan then cycles on/off to control heating / cooling output. The controls are often a wall mounted thermostat with hand selection of heating/cooling and fan speed (off/low/medium/high). These controls may also be mounted on the unit

Carrier offers a retrofit VSD motor for fan coil units. It claims up to 45% energy savings from such a retrofit, as well as increased comfort and less noise compared to a cycling fan (fan coil fans are typically noisy and inefficient). Some other manufacturers are also offering units with VSD fans. Variable speed fans appear to offer an easy way to significantly increase the efficiency of what have typically been very inefficient units.

EnergyPlus provides 4 capacity control methods for this unit: 1) multi-speed cycling fan with constant water flow rate; 2) constant speed continuous fan with variable water flow rate; 3) variable-speed fan with constant water flow rate; 4) variable-speed fan with variable water flow rate.

In EnergyPlus the fan coil units are modeled as compound components. That is, they are assembled from other components. Fan coils contain an outdoor air mixer, a fan, a heating coil and a cooling coil. These components are described elsewhere in this document. The fan coil input simply requires the names of these four components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, outdoor airflow rate, and maximum and minimum hot and cold water volumetric flow rates. The unit is connected to the zone inlet and exhaust nodes and the outdoor air by specifying unit inlet, and outlet air node names and the outdoor air mixer object name. The outdoor air mixer child object provides the outdoor air and relief air nodes names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node. The fan coil unit is connected to a hot water loop (demand side) through its hot water coil and to a chilled water loop (demand side) through its cooling coil.

Note that the type of fan component associated with the fan coil unit depends on the type of capacity control method chosen. For *ConstantFanVariableFlow* a *Fan:OnOff* or *Fan:ConstantVolume* should be used. For *CyclingFan*, a *Fan:OnOff* should be used. And for *VariableFanVariableFlow* or *VariableFanConstantFlow* a *Fan:VariableVolume* should be chosen.

Fan coil units can be 4-pipe or 2-pipe. For 4-pipe units there are 2 supply pipes and 2 return pipes. For 2-pipe units there is a single supply pipe and a single return pipe and the supply is switched between hot and chilled water depending on the season. We model 4-pipe units, but the 4-pipe model can be used to model 2-pipe units by using the coil availability schedules to make sure that either hot or chilled water is exclusively available.

Field: Name

A unique user assigned name for an instance of a Fan Coil unit. Any reference to this Fan Coil unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the fan coil unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit

can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Capacity Control Method

This input denotes how the unit's output is controlled in order to meet zone heating or cooling requirement. The choices are *ConstantFanVariableFlow*, *CyclingFan*, *VariableFanVariableFlow* or *VariableFanConstantFlow*. For *ConstantFanVariableFlow*, the fan speed is held constant to produce a fixed air flow rate whenever the unit is scheduled on. The hot water or chilled flow rate is varied so that the unit output matches the zone heating or cooling requirement. For *CyclingFan*, the fan speed is chosen so that the unit capacity is greater than or equal to the heating / cooling load and the fan is cycled to match unit output with the load. For *VariableFanVariableFlow* both air and water flow rates are varied to match the load. For *VariableFanConstantFlow*, the water flow rate is at full flow and the fan speed varies to meet the load.

Field: Maximum Supply Air Flow Rate

The maximum volumetric airflow rate (m^3/sec) through the fan coil unit. This is also the design, rated airflow rate of the unit.

Field: Low Speed Supply Air Flow Ratio

This numerical field specifies the ratio of the low speed flow rate to the maximum supply air flow rate. Its value should be less than *Medium Speed Supply Air Flow Ratio*. If left blank, the default value is 0.33. Leave it blank if the capacity control method selected is not *CyclingFan*.

Field: Medium Speed Supply Air Flow Ratio

This numerical field specifies the ratio of the medium speed flow rate to the maximum supply air flow rate. Its value should be greater than the *Low Speed Supply Air Flow Ratio* but less than 1. If left blank, the default value is 0.66. Leave it blank if the capacity control method selected is not *CyclingFan*.

Field: Maximum Outdoor Air Flow Rate

If the fan coil unit uses outdoor air, this field specifies the outdoor air volumetric flow rate (m^3/sec). This flow rate should be less than or equal to the maximum airflow rate. A value of zero specifies no outdoor air.

Field: Outdoor Air Schedule Name

The name of a schedule whose values (0.0 to 1.0) are used as multipliers to alter the outdoor air flow rate. If this field is left blank, the values will default to 1.0.

Field: Air Inlet Node Name

The name of the HVAC system node from which the fan coil unit draws its indoor air. This should be one of zone exhaust nodes for the zone which the fan coil unit is serving.

Field: Air Outlet Node Name

The name of the HVAC system node to which the fan coil unit sends its outlet air. This should be one of the inlet air nodes of the zone which is being served.

Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this fan coil unit. The outdoor air mixer component is part of the fan coil compound object. The only available outdoor air mixer type is:

OutdoorAir:Mixer

Field: Outdoor Air Mixer Name

The name of an outdoor air mixer component (object: *OutdoorAir:Mixer*) which composes part of the fan coil unit. Note that the return air node of the outdoor air mixer should be the same node as the air inlet node of the fan coil unit. In addition, the outdoor air mixer's mixed air node should be the same as the inlet air node of the fan coil unit's fan.

Field: Supply Air Fan Object Type

This field specifies the type of supply air fan object used by this fan coil. The supply air fan is part of the fan coil compound object. The only valid supply air fan types are:

```
Fan:OnOff
Fan:ConstantVolume
Fan:VariableVolume
```

Field: Supply Air Fan Name

The name of a fan component that composes part of the fan coil unit. Note that the fan's maximum flow rate should be the same as the maximum airflow rate of the fan coil unit and the type of fan object should correspond to the capacity control method. Namely, for *ConstantFanVariableFlow* a *Fan:OnOff* or *Fan:ConstantVolume* should be used. For *CyclingFan*, a *Fan:OnOff* should be used. And for *VariableFanVariableFlow* or *VariableFanConstantFlow* a *Fan:VariableVolume* should be chosen. The fan's inlet node should be the same as the outdoor air mixer's mixed air node.

The fan's outlet node should be the same as the cooling coil's air inlet node.

Field: Cooling Coil Object Type

This field specifies the type of chilled water cooling coil to be modeled for this fan coil unit. Only the following coil types can be used:

```
Coil:Cooling:Water
Coil:Cooling:Water:DetailedGeometry
CoilSystem:Cooling:Water:HeatExchangerAssisted
```

The input requirements for these chilled water coil objects are described elsewhere in this document.

Field: Cooling Coil Name

The name of the cooling coil component that composes part of the fan coil unit. The cooling coil air inlet node should be the same as the fan outlet node. The cooling coil air outlet node should be the same as the heating coil air inlet node.

Only the following coil types can be used:

```
Coil:Cooling:Water
Coil:Cooling:Water:DetailedGeometry
CoilSystem:Cooling:Water:HeatExchangerAssisted
```

Field: Maximum Cold Water Flow Rate

The maximum cold water volumetric flow rate (m^3/sec) through the fan coil unit's cooling coil.

Field: Minimum Cold Water Flow Rate

The minimum cold water volumetric flow rate (m^3/sec) through the fan coil unit's cooling coil.

Field: Cooling Convergence Tolerance

The convergence tolerance for the control of the unit cooling output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The cooling convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{fancoil,out} - Q_{zoneload}|}{Q_{zoneload}} \leq CoolingConvergenceTolerance$$

Field: Heating Coil Object Type

This field is the type of coil that is used for heating in the fan coil system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. The only allowable heating coil type is:

Coil:Heating:Water

Field: Heating Coil Name

The name of the heating coil component that composes part of the fan coil unit. The heating coil air inlet node should be the same as the cooling coil outlet node. The heating coil air outlet node should be the same as the fan coil air outlet node.

Only the following coil type can be used:

Coil:Heating:Water

Field: Maximum Hot Water Flow Rate

The maximum hot water volumetric flow rate (m^3/sec) through the fan coil unit's heating coil.

Field: Minimum Hot Water Flow Rate

The minimum hot water volumetric flow rate (m^3/sec) through the fan coil unit's heating coil.

Field: Heating Convergence Tolerance

The convergence tolerance for the control of the unit heating output. The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{fancoil,out} - Q_{zoneload}|}{Q_{zoneload}} \leq HeatingConvergenceTolerance$$

Ideal Loads Hybrid Ventilation Availability Status []

This is the availability status of the ideal loads object as set by the hybrid ventilation manager. Rules to determine the availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 and 1. These integers represent NoAction (0) and ForceOff (1). When the availability status is ForceOff, the unit is turned off regardless of its availability schedule. The other status flag i.e. NoAction does not control the unit and the controls of the unit turn it back on. Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the "detailed" reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

An example input for a fan coil unit, including its constituent components, is shown below.

Fan Coil Heating Rate[W]

This field reports the dry air heating addition rate of the fan coil unit to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit.

Fan Coil Heating Energy[J]

This field is the dry air heat addition of the fan coil unit to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

Fan Coil Total Cooling Rate[W]

This field is the total (sensible and latent) heat extraction rate of the fan coil unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Fan Coil Total Cooling Energy[J]

This field is the total (sensible and latent) heat extraction of the fan coil unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

Fan Coil Sensible Cooling Rate[W]

This field reports the dry air sensible heat extraction rate of the fan coil unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Fan Coil Sensible Cooling Energy[J]

This field is the dry air sensible heat extraction of the fan coil unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions, the mass flow rate through the unit, and the timestep.

Fan Coil Electric Power[W]

This field reports the electricity consumption rate of the fan coil unit in Watts.

Fan Coil Electric Consumption[J]

This field is the electricity consumption of the fan coil unit in Joules over the timestep being reported.

Fraction Of Timestep Fancoil is ON

This field is the fraction of the system timestep the fan coil unit is running for the *CyclingFan* capacity control method. This variable is defined only for the *CyclingFan* capacity control method.

Fan Speed

This field indicates the speed chosen for the fan in the *CyclingFan* capacity control method. A value of '0' means that the unit is off, '1' the fan is running at its low speed, '2' medium speed, and '3' high speed (maximum). This variable is defined only for the *CyclingFan* capacity control method.

Part Load Ratio

When the capacity control method is *VariableFanVariableFlow* or *VariableFanConstantFlow*, this output variable reports the unit part load ratio (ratio of unit heating / cooling output to the maximum heating / cooling output). This variable is defined only for *VariableFanVariableFlow* or *VariableFanConstantFlow* capacity control methods.

Fan Coil Fan Availability Status

This is the availability status of the fan coil unit fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the fan coil unit object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:^{*} Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the "detailed" reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:UnitVentilator

Unit ventilators are zone equipment units which are assembled from other components. They contain a built-in outdoor air mixer, a fan, a heating coil, and a cooling coil. These components are described elsewhere in this document, except the built-in outdoor air mixer which is contained within the unit ventilator statement. The unit ventilator input simply requires the names of these other three components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, outdoor air control information (control type and schedules), an outdoor airflow rate, and maximum and minimum hot and cold water mass flow rates. The unit is connected to the zone inlet and exhaust nodes and the outdoor air by specifying unit inlet, outlet, outdoor air and exhaust (relief) air node names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node. In general, the unit ventilator input is very similar to the fan coil unit input, and the unit is connected to a hot water loop (demand side) through its hot water coil and to a chilled water loop (demand side) through its cooling coil.

The main difference between the fan coil and unit ventilator input is that the unit ventilator has a built-in outdoor air mixer with its own specialized controls. The outdoor air control type can be selected from one of the following options: "variable percent", "fixed temperature" or "fixed amount". In fixed temperature control, the amount of outdoor air is varied between the minimum outdoor air fraction (specified by a schedule) and 100% outdoor air to obtain a mixed air temperature as close as possible to the temperature schedule defined in the input. Variable percent control will also vary the amount of outdoor air between the minimum and maximum fractions (both specified in input by the user) to meet the load without the use of a coil if possible. In fixed amount control, the outdoor air flow rate is fixed to the specified value by the user. In this control strategy, the maximum outdoor air flow rate and schedule are automatically set to be equal to the minimum outdoor air flow rate and schedule. These control types are based on the 2004 ASHRAE Systems and Equipment Handbook (pp. 31.1-31.3) description of unit ventilator systems.

The unit is controlled to meet the zone (remaining) heating or cooling demand. If there is a heating demand, the cooling coil is off and the hot water flow through the heating coil is throttled to meet the demand. The hot water control node must be specified (same as the hot water coil inlet node). If there is a cooling demand from the zone, the hot water coil is off and the chilled water flow through the cooling coil is throttled to meet the load. The cooling coil control node must be specified (same as the cooling coil inlet node). Finally both heating and cooling require a convergence tolerance, which is the tolerance denoting how closely the fan coil unit will meet the heating or cooling load. The tolerance is always relative to the zone load.

Overall, control of the unit must consider the outdoor air. Here is a more detailed description of the overall unit control:

Off: Unit is schedule off or there is no load on it. All flow rates are set to zero and the temperatures are set to zone conditions (except for the outdoor air inlet). Outdoor air requirements will not override this condition.

Heating/No Coil/VariablePercent: The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and variable percent outdoor air control type has been specified. In this case, the variable percent outdoor air controls what happens with the outdoor air. If the outside temperature is greater than the return temperature, then the outdoor air is set to the maximum as defined by the user input. If the outdoor air temperature is less than the return temperature from the zone, then the outdoor air is set to the minimum outdoor air flow rate as defined by the user. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

Heating/No Coil/FixedTemperature: The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate.

Heating/No Coil/FixedAmount: The unit is on, there is a heating load, no heating coil is present or it has been scheduled off, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

Heating /With Coil/VariablePercent: The unit is on, there is a heating load, and variable percent control is specified. The outdoor air fraction is set to the minimum outdoor air fraction (schedule based), and the heating coil is activated. The heating coil attempts to meet the remaining load on the zone being served by the unit ventilator.

Heating /With Coil/FixedAmount: The unit is on, there is a heating load, a heating coil is present and is scheduled on, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. The heating coil then attempts to meet any remaining zone heating load.

Cooling/No Coil/VariablePercent: The unit is on, there is a cooling load, no coil is present or it has been scheduled off, and variable percent outdoor air control type has been specified. In this case, the variable percent outdoor air controls what happens with the outdoor air. If the outside temperature is greater than the return temperature, then the outdoor air is set to the minimum as defined by the user input. If the outdoor air temperature is less than the return temperature from the zone, then the outdoor air is set to the maximum outdoor air flow rate as defined by the user. This may be somewhat simplistic in that it could result in overcooling of the space. However, since a temperature goal was not established, this is the best that can be done by the simulation. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outdoor air controls.

Cooling/No Coil/FixedTemperature: The unit is on, there is a cooling load, no cooling coil is present or it has been scheduled off, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate in the same fashion as the variable percent outdoor air control.

Cooling/No Coil/FixedAmount: The unit is on, there is a cooling load, no cooling coil is present or it has been scheduled off, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. Since a coil is not present to further condition the supply air, the zone simply receives whatever temperature air results from the outside air controls.

Cooling/With Coil/VariablePercent: The unit is on, there is a cooling load, a coil is present and is scheduled on, and variable percent outdoor air control type has been specified. In this case, the percentage of outdoor air is set to the minimum flow outdoor air flow rate. The coil then attempts to meet any remaining zone load.

Cooling/With Coil/FixedTemperature: The unit is on, there is a cooling load, a cooling coil is present and is scheduled on, and fixed temperature has been specified. The unit ventilator tries to use outdoor air as best as possible to meet the temperature goal. If it cannot meet this goal because the temperature goal is not between the zone return temperature and the outdoor air temperature, then the unit ventilator will either use the maximum or minimum outdoor air flow rate in the same fashion as the fixed temperature outdoor air control for the “no coil” conditions. The cooling coil then attempts to meet any remaining zone load.

Cooling/With Coil/FixedAmount: The unit is on, there is a cooling load, a cooling coil is present and is scheduled on, and fixed amount control has been specified. The unit ventilator fixes the outdoor air flow rate as defined by the user and sets the maximum and minimum outdoor air flow rate to be equal in order to avoid the variation of outdoor air flow rate between the maximum and minimum values. The cooling coil then attempts to meet any remaining zone cooling load.

Note: the unit ventilator controls are strictly temperature based and do not factor humidity into the equation (not an enthalpy economy cycle but rather a simple return air economy cycle). In addition, temperature predictions are not strict energy balances here in the control routine though in the mixing routine an energy balance is preserved.

Field: Name

This field is simply the identifying name that distinguishes one particular unit ventilator from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other unit ventilators use this same name.

Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the unit ventilator is available to operate. The schedule is interpreted as a digital switch. If the schedule value of the unit ventilator availability schedule for a particular time frame is less than or equal to zero, then the unit ventilator is unavailable and will not operate. For any schedule value greater than zero, the unit ventilator is considered available and may operate, if necessary.

Field: Maximum Supply Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the unit ventilator system in m^3/sec . This parameter should be some real number greater than zero.

Field: Outdoor Air Control Type

This field allows the user to control how outdoor air is used in the unit ventilator system. The unit ventilator system described by this syntax has its own outdoor air handler. The three options for outdoor air control are “**VariablePercent**”, “**FixedTemperature**” and “**FixedAmount**”. Those keys are the only allowed choices for this parameter. In general, the variable percent control will attempt to vary the amount of outdoor air between some minimum and maximum schedules of fractions (see next two fields) to best meet the current heating or cooling load. The fixed temperature control will vary the amount of outdoor air between the minimum schedule (fraction of maximum, see next field) and 100% available

outdoor air to come as close as possible to a desired mixed air temperature (see 2 fields down) that can be scheduled. The fixed amount control will fix the outdoor air flow rate as minimum outdoor air flow rate and schedule specified by the user and automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate. More information on the controls and operation of the unit ventilator are given in the introductory section above.

Field: Minimum Outdoor Air Flow Rate

This field allows the user to enter the minimum volumetric flow rate of outdoor air (in m^3/sec) that will be brought in to the unit ventilator. The actual minimum outdoor air flow rate will be this number multiplied by the schedule value from the minimum outdoor air schedule. If “FixedAmount” type is selected as the outdoor air control strategy, the outdoor air flow rate will be fixed as this field and the unit ventilator will automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate.

Field: Minimum Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that should contain values for the minimum outdoor air used by the unit ventilator system for IAQ or other reasons. Note that if the unit ventilator is scheduled off or if there is no load sensed in the zone that the system will not operate even to achieve the minimum air fraction. However, if the system is operating, it will always bring in this fraction of the minimum air flow rate (see minimum air flow rate field above). If “FixedAmount” type is selected as the outdoor air control strategy, the actual outdoor air flow rate will be this number multiplied by the minimum outdoor air flow rate in the field above. The unit ventilator will automatically set the maximum and minimum outdoor air schedule to be equal by ignoring the maximum outdoor air schedule.

Field: Maximum Outdoor Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of outdoor air that can be brought into the unit ventilator system in m^3/sec . This parameter should be some real number greater than zero. Note that the value for this parameter may be less than the maximum air flow rate of the unit ventilator and this may affect the maximum fraction of outdoor air within the control strategy defined above. This parameter is an absolute maximum and will supersede any scheduled fraction of the unit ventilator maximum airflow rate. If “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air flow rate specified in the field above.

Field: Maximum Outdoor Air Fraction or Temperature Schedule Name

This field can have one of two meanings depending the type of control selected in the outdoor air control type parameter above. If “VariablePercent” or “FixedAmount” was selected, then this field is a schedule name (ref: Schedule) corresponding to a maximum air fraction schedule. Furthermore, if “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air fraction specified in the field below. Note that this is a fraction of the maximum airflow rate field (see parameter above) for the unit ventilator. If “FixedTemperature” control was selected, then this field is still a schedule name (ref: Schedule), but it corresponds to a schedule of mixed air temperatures that the outdoor air control will try to attain.

Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the unit ventilator. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit ventilator, the air inlet node to the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) to the unit ventilator. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit ventilator, the air outlet node from the system will typically be the same node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Outdoor Air Node Name

This field is a node name used to identify the node associated with fresh air brought into the unit ventilator from the outdoor environment. You should also have defined an OutdoorAir:Node object with the same name and assign it an optional height (above ground).

Field: Exhaust Air Node Name

This field is a node name used to identify the node associated with air exhausted out of the unit ventilator to the outdoor environment. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the unit ventilator.

Field: Mixed Air Node Name

This field is a node name used to identify the node associated with the “mixed” air of the unit ventilator. These conditions are post-“mixing box” since they are the conditions of the fraction of return air combined with the outdoor air. Since this is a simple system, this can also be viewed as the conditions of the air being sent to the coils. While from a simulation standpoint this name is arbitrary and not a “necessity”, assigning a name to this node allows the user to receive output on conditions at this node to verify the correct operation of the unit ventilator.

Field: Supply Air Fan Object Type

This field specifies the type of supply air fan used by this unit ventilator. The supply air fan is part of the unit ventilator compound object. The only valid supply air fan types are:

Fan:ConstantVolume
Fan:VariableVolume

Field: Supply Air Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume, Fan: VariableVolume) that is part of the unit ventilator system. This name links the unit ventilator to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the unit ventilator system.

Field: Coil Option

This field allows the user to specify the coil operating options as one of the following options: **None**, **Heating**, **Cooling** or **HeatingAndCooling**. If **None** is selected, the unit ventilator does not have any coils, and any other input will be ignored. If either **Heating** or **Cooling** is selected, only a heating or cooling coil, respectively, is present. Thus, only four more inputs will be expected. If **HeatingAndCooling** is selected, both heating and cooling coil input must be entered, and the unit ventilator will have both a heating and a cooling coil.

Field: Heating Coil Object Type

This field is the type of coil that is used for heating in the unit ventilator system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. Allowable heating coil types are:

Coil:Heating:Water
Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Steam

Field: Heating Coil Name

This field is the name of the heating coil that is part of the unit ventilator system. It is assumed that there is always some sort of heating coil associated with a unit ventilator system. This name links the unit ventilator to particular heating coil data entered elsewhere in the input data file.

Field: Heating Convergence Tolerance

The control tolerance for the unit heating output. This field allows the user some control over how closely the heating coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point. This field is ignored for gas and electric heating coils.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{UnitVentilator,Out} - Q_{ZoneLoad}|}{Q_{ZoneLoad}} \leq HeatingConvergenceTolerance$$

Field: Cooling Coil Object Type

This field is the type of coil that is used for cooling in the unit ventilator system. It is used in conjunction with the cooling coil name (see next field) to specify the cooling coil present within the system.

Only the following coil types can be used:

Coil: Cooling: Water
 Coil: Cooling: Water: DetailedGeometry
 CoilSystem: Cooling: Water: HeatExchangerAssisted

Field: Cooling Coil Name

This field is the name of the cooling coil that is part of the unit ventilator system. This name links the unit ventilator to particular cooling coil data entered elsewhere in the input data file. Note that a cooling coil is not a required part of a unit ventilator system. If no cooling coil is present, the previous field may be followed by a semi-colon and the remaining parameters in this statement may be ignored.

Field: Cooling Convergence Tolerance

The convergence tolerance for the unit cooling output. This field allows the user some control over how closely the cooling coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The cooling convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{UnitVentilator,Out} - Q_{ZoneLoad}|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance$$

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this unit ventilator object's fan. If the unit ventilator is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this unit ventilator object should be on or off.

An example input for a unit ventilator, including its constituent components, is shown below.

HVAC,Average,Unit Ventilator Fan Electric Power[W]
HVAC,Sum,Unit Ventilator Fan Electric Consumption[J]
HVAC,Average,Unit Ventilator Fan Availability Status[]

Unit Ventilator Heating Rate[W]

This field reports the heating output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

Unit Ventilator Heating Energy[J]

This field is the heating output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

Unit Ventilator Total Cooling Rate[W]

This field reports the total cooling (sensible plus latent) output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

Unit Ventilator Total Cooling Energy[J]

This field is the total cooling (sensible plus latent) output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

Unit Ventilator Sensible Cooling Rate[W]

This field reports the sensible cooling output rate of the unit ventilator system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit ventilator.

Unit Ventilator Sensible Cooling Energy[J]

This field is the sensible cooling output of the unit ventilator system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit ventilator, and the timestep.

Unit Ventilator Fan Electric Power[W]

This field reports the electric power consumption rate of the fan of the unit ventilator in Watts.

Unit Ventilator Fan Electric Consumption[J]

This field reports the electric power consumed by the fan of the unit ventilator over the timestep in Joules.

Unit Ventilator Fan Availability Status[]

This is the availability status of the unit ventilator fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the unit ventilator object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:** Outputs*). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:UnitHeater

Unit heaters are zone equipment units which are assembled from other components and are a simplification of unit ventilators. They contain only a fan and a heating coil. These components are described elsewhere in this document. The unit heater input simply requires the names of these components, which have to be described elsewhere in the input. The input also requires the name of an availability schedule, maximum airflow rate, and maximum and minimum hot water volumetric flow rates. The unit is connected to the zone inlet and exhaust nodes by specifying unit inlet and outlet node names. Note that the unit air inlet node should be the same as a zone exhaust node and the unit outlet node should be the same as a zone inlet node.

While the control of the heating coil is similar to the fan coil units and the unit ventilator, the overall control of the unit heater is much different. There are four different modes in which a unit heat can operate based on the user input:

Off: Unit is schedule off. All flow rates are set to zero and the temperatures are set to zone conditions.

NoLoad OR Cooling/OnOff Fan Control: Unit is available, but there is no heating load. All flow rates are set to zero and the temperatures are set to zone conditions.

NoLoad OR Cooling/Continuous Fan Control: Unit is available and the fan is running (if it is scheduled to be available also). No heating is provided, only circulation via the fan running.

Heating: The unit is on/available and there is a heating load. The heating coil is modulated (constant fan speed) to meet the heating load.

Control of the heating coil and its flow rate is identical to the fan coil unit and unit ventilator.

Field: Name

This field is simply the identifying name that distinguishes one particular unit heater from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other unit heaters use this same name.

Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the unit heater is available to operate. The schedule is interpreted as a digital switch. If the schedule value of the unit heater availability schedule for a particular time frame is less than or equal to zero, then the unit heater is unavailable and will not operate. For any schedule value greater than zero, the unit heater is considered available and may operate.

Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the unit heater. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit heater, the air inlet node to the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) to the unit heater. In EnergyPlus, nodes represent points between components or at various points in the loops. In a unit heater, the air outlet node from the system will typically be the same node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Supply Air Fan Object Type

This field specifies the type of supply air fan used by this unit heater. The supply air fan is part of the unit heater compound object. The only valid supply air fan types are:

Fan:ConstantVolume
Fan:VariableVolume

Field: Supply Air Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume, Fan:VariableVolume) that is part of the unit heater system. This name links the unit heater to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the unit heater system.

Field: Maximum Supply Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the unit heater system in m^3/s . This parameter should be some real number greater than zero.

Field: Fan Control Type

This field allows the user to define how the unit heater will operate under “no load” or cooling conditions. The user may select from two options. If the “OnOff” control is selected, then the fan will not run unless there is a heating load. If the fan does not run, this effectively shuts the

unit heater system off (there is no option to simply run the heating coil and allow natural convection to transfer heat from the unit to the zone). If the “**Continuous**” control is selected, then the fan will always run if the unit heater is available. This will produce air movement in the zone but also add some amount of heat to the energy balance since the fan will generate some heat. For more information on controlling the operation of the unit heater, see the general description given above.

Field: Heating Coil Object Type

This field is the type of coil that is used for heating in the unit heater system. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system. Allowable heating coil types are:

Coil:Heating:Water
 Coil:Heating:Electric
 Coil:Heating:Gas
 Coil:Heating:Steam

Field: Heating Coil Name

This field is the name of the heating coil that is part of the unit heater system. It is assumed that there is always some sort of heating coil associated with a unit heater system. This name links the unit ventilator to particular heating coil data entered elsewhere in the input data file.

Field: Maximum Hot Water or Steam Flow Rate

This field allows the user to enter a maximum volumetric flow rate of water through a water heating coil in m³/sec. This number should be some number greater than zero and greater than the minimum hot water volumetric flow rate (see next field). Note that this parameter has no meaning for either an electric or a gas heating coil.

Field: Minimum Hot Water or Steam Flow Rate

This field allows the user to enter a minimum volumetric flow rate of water through a water heating coil in m³/sec. This number should be some number greater than zero and less than the maximum hot water volumetric flow rate (see previous field). Note that this parameter has no meaning for either an electric or a gas heating coil.

Field: Heating Convergence Tolerance

The convergence tolerance for the unit heating output. This field allows the user some control over how closely the heating coil will control the air side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in supply conditions (that could in turn result in excessive iterations). Initial experience with this parameter lends to the recommendation of using 0.001 as a starting point. This field is ignored for gas and electric heating coils.

The unit is controlled by matching the unit output to the zone demand. For units with water coils, the model must be numerically inverted to obtain a specified output. The heating convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|Q_{\text{unitheater,out}} - Q_{\text{zoneload}}|}{Q_{\text{zoneload}}} \leq \text{HeatingConvergenceTolerance}$$

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability

Manager type and name. The availability managers in the list apply to this unit heater object's fan. If the unit heater is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this unit heater object should be on or off.

An example input for a unit heater, including its constituent components, is shown below.

Unit Heater Outputs

HVAC,Average,Unit Heater Heating Rate[W]
HVAC,Sum,Unit Heater Heating Energy[J]
HVAC,Average,Unit Heater Fan Electric Power[W]
HVAC,Sum,Unit Heater Fan Electric Consumption[J]
HVAC,Average, Unit Heater Fan Availability Status[]

Unit Heater Heating Rate[W]

This field reports the heating output rate of the unit heater system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the unit heater.

Unit Heater Heating Energy[J]

This field is the heating output of the unit heater system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit heater, and the timestep.

Unit Heater Fan Electric Power[W]

This field reports the electric power consumption rate of the fan of the unit heater in Watts.

Unit Heater Fan Electric Consumption[J]

This field reports the electric power consumed by the fan of the unit heater over the timestep in Joules.

Unit Heater Fan Availability Status

This is the availability status of the unit heater fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the unit heater object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:OutdoorAirUnit

The zone outdoor air unit (ZoneHVAC:OutdoorAirUnit) in EnergyPlus is intended to model dedicated outdoor air systems (DOAS) and other similar systems which aim to provide either additional outside air or some limited amount of sensible and/or latent conditioning. The zone outdoor air unit is a piece of zone equipment that can consist of a supply fan, an exhaust fan (optional), heating and cooling coils, and heat recovery. The outdoor air unit input simply requires information about flow rates, schedules, node names, and a list of component that are part of the unit. These components require additional input as per the requirements for these components. In addition, the input includes information about controls for the unit. It should be noted that the components that make up the zone outdoor air unit do not require additional controls or setpoints. The unit input defines how the unit outlet temperature is controlled as described below.

Figure 97. Zone Outdoor Air Unit Schematic

Zones may contain one or more zone outdoor air units. The user can choose to have each unit have its own exhaust fan or may choose to have only one unit have an exhaust fan that will handle the flow of all of the zone outdoor air units. Note that the user will need to account for any flow balance among the zone outdoor air units on the supply and exhaust sides.

The full input for zone outdoor air units is described below using a variety of fields.

Field: Name

This field is simply the identifying name that distinguishes one particular outdoor air unit from another in the input data file. Like all other names in EnergyPlus, it is assumed that this is a unique character string and that no other zone outdoor air units use this same name.

Field: Availability Schedule Name

This field is a schedule name (ref: Schedule) that determines whether the zone outdoor air unit is available to operate. The schedule is interpreted as a digital switch. If the schedule value of the outdoor air unit availability schedule for a particular time frame is less than or equal to zero, then the outdoor air unit is unavailable and will not operate. For any schedule value greater than zero, the outdoor air unit is considered available and will operate at the supply and exhaust flow rates defined by input field described below.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the outdoor air unit is located and intended to affect. Zone outdoor air units impact only a single zone.

Field: Outdoor Air Flow Rate

This field allows the user to enter the volumetric flow rate of outdoor air (in m^3/sec) that will be brought in through the outdoor air unit. The actual outdoor air flow rate will be this number multiplied by the schedule value from the outdoor air schedule. This field is autosizable. When autosized, the unit's outdoor air flow rate will match the minimum outdoor air requirements specified through the Sizing:Zone object.

Field: Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that contains values for modifying the outdoor air flow rate. The supply air flow rate is the product of the outdoor air flow rate and the outdoor air schedule value for the time of interest. Note that if the outdoor air unit is scheduled off that the system will not operate regardless of the outdoor air schedule value. However, if the system is operating, it will always bring in this fraction of the outdoor air flow rate.

Field: Supply Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume, Fan: VariableVolume) that is part of the zone outdoor air unit. This name links the outdoor air unit to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the outdoor air control unit.

Field: Fan Placement

This field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. It means that the unit consists of outdoor air node followed by a supply fan followed by the equipment that are part of the system. The second choice stands for “draw through fan”. It means that the supply fan placed at the end of supply air stream and supply fan outlet node is identified with the air outlet node. The fan “draws air through” the equipment system.

BlowThrough
DrawThrough

If the user does not select a fan placement type, **DrawThrough** is assumed as default by EnergyPlus.

Field: Exhaust Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume, Fan: VariableVolume) that is part of the outdoor air unit. This name links the outdoor air unit to particular fan data entered elsewhere in the input data file. This field is optional.

Field: Exhaust Air Flow Rate

This field allows the user to enter the volumetric flow rate of air (in m³/sec) that will be exhausted to the outdoors. The actual exhaust air flow rate will be this number multiplied by the schedule value from the exhaust air schedule. If the exhaust fan name is left blank, this field will be ignored and automatically set to be equal to zero.

Field: Exhaust Air Schedule Name

This field contains a schedule name (ref: Schedule) that should contain values for modifying the exhaust air flow rate. The actual exhaust air flow rate equals the exhaust air flow rate input (previous field) multiplied by the exhaust air schedule value. If the exhaust fan name is left blank, this field will be ignored and automatically set to be equal to zero.

Field: Unit Control Type

The unit control type field determines with conditions in the zone being served what the response of the zone outdoor air system will be. It is important to note that this only controls the temperature of the air being delivered to the space not whether or not the system will operate. There are two options for this field: Neutral or Temperature. Neutral control tries to have no energy impact on the zone by delivering air at the temperature of the zone. This allows air to be delivered to the zone without affecting the zone air heat balance and thus provides outside air without impacting any other system providing conditioning to this zone. The temperature control option will supply air to the zone based on the high and low air control temperature schedules (see next two fields). For temperature control, when the outside air temperature is less than the low air control temperature, the zone outdoor air unit

will provide whatever heating is available from its components to achieve the low air temperature value. When the outside air temperature is above the high air control temperature, the zone outdoor air unit will provide whatever cooling is available from its components to achieve the high air temperature value. When the outdoor air temperature is between the high and low air control temperatures, the unit will simply provide air at whatever the outdoor air conditions are, modified by any fan heat added by the supply fan. In summary, the user must select from the following two options:

NeutralControl
TemperatureControl

If the user does not select a unit control type, **NeutralControl** is assumed as the default by EnergyPlus.

Field: High Air Control Temperature Schedule Name

This field specifies the dry-bulb air temperature in degrees Celsius for the supply air temperature to the zone. When the outdoor air temperature or post-supply fan outlet temperature in the case of blow through is above the high air control temperature, a cooling coil, if available and specified by the user, is tuned on to conditioning the outdoor air to the high control temperature. This field only applies to zone outdoor air units that use Temperature Control (see previous field).

Field: Low Air Control Temperature Schedule Name

This field specifies the dry-bulb air temperature in degrees Celsius for the supply air temperature to the zone. When the outdoor air temperature or post-supply fan outlet temperature is below the low air control temperature, a heating coil, if available and specified by the user, is tuned on to conditioning the outdoor air to the low control temperature. This field only applies to zone outdoor air units that use Temperature Control (see two previous fields).

Field: Outdoor Air Node Name

This field is a node name used to identify the node associated with fresh air brought into the outdoor air unit from the outdoor environment. It should also be defined in an **OutdoorAir:Node** object with the same name and assigned an optional height (above ground).

Field: Air Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) from the zone outdoor air unit. In EnergyPlus, nodes represent points between components or at various points in the loops. In an outdoor air unit, the air outlet node from the system will typically be the same node as a zone inlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Air Inlet Node Name

This field is a node name used to identify the node that serves as the inlet (air side) to the exhaust side of the outdoor air unit. In EnergyPlus, nodes represent points between components or at various points in the loops. In an outdoor air unit, the air inlet node of the system will typically be the same node as a zone outlet node. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Supply Fan Outlet Node Name

This field is a node name used to identify the node that serves as the outlet (air side) of the supply fan for the zone outdoor air unit. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Outdoor Air Unit List Name

This field is the name of an ZoneHVAC:OutdoorAirUnit:EquipmentList object. An ZoneHVAC:OutdoorAirUnit:EquipmentList is simply a list of components giving both component name and type. This equipment list specifies all the components that will be simulated in this unit. The order of the components in the list is significant: components are simulated sequentially in the order given in the Equipment List.

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this outdoor air unit object's fan. If the outdoor air unit is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this outdoor air unit object should be on or off.

An example of this object defined in an input data file is shown below:

```
ZoneHVAC:OutdoorAirUnit,
  Zone5DXOutAir,           ! - Name
  OAUnitOASched,          ! - Availability Schedule Name
  SPACE5-1,               ! - Zone Name

ZoneHVAC:OutdoorAirUnit Outputs

HVAC,Average,Outdoor Air Unit Heating Rate[W]
HVAC,Sum, Outdoor Air Unit Heating Energy[J]
HVAC,Average, Outdoor Air Unit Total Cooling Rate[W]
HVAC,Sum, Outdoor Air Unit Total Cooling Energy[J]
HVAC,Average, Outdoor Air Unit Sensible Cooling Rate[W]
HVAC,Sum, Outdoor Air Unit Sensible Cooling Energy[J]
HVAC,Average, Outdoor Air Unit Unit Fan Electric Power[W]
HVAC,Sum, Outdoor Air Unit Fan Electric Consumption[J]
HVAC,Average, Outdoor Air Unit Air Mass Flow Rate[kg/s]
HVAC,Average, Outdoor Air Unit Fan Availability Status []

Outdoor Air Unit Heating Rate [W]

This field reports the heating output rate of the outdoor air unit system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the zone outdoor air unit.

Outdoor Air Unit Heating Energy [J]

This field is the heating output of the outdoor air unit system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

Outdoor Air Unit Total Cooling Rate [W]

This field reports the total cooling (sensible plus latent) output rate of the outdoor air unit system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the zone outdoor air unit.

Outdoor Air Unit Total Cooling Energy [J]

This field is the total cooling (sensible plus latent) output of the outdoor air unit system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

Outdoor Air Unit Sensible Cooling Rate [W]

This field reports the sensible cooling output rate of the outdoor air unit system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the zone outdoor air unit.

Outdoor Air Unit Sensible Cooling Energy [J]

This field is the sensible cooling output of the outdoor air unit system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the zone outdoor air unit, and the time step.

Outdoor Air Unit Fan Electric Power [W]

This field reports the electric power consumption rate of the fan of the outdoor air unit in Watts.

Outdoor Air Unit Fan Electric Consumption [J]

This field reports the electric power consumed by the fan of the outdoor air unit over the time step in Joules.

Outdoor Air Unit Air Mass Flow Rate [kg/s]

This field reports the air mass flow rate of the zone outdoor air unit Outdoor Air Unit in kilograms per second.

Outdoor Air Unit Fan Availability Status []

This is the availability status of the outdoor air unit fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the outdoor air unit object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:`*` Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the "detailed" reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:OutdoorAirUnit:EquipmentList

This input syntax is used to specify the components in a zone outdoor air unit. The components will be simulated in the order in which they occur in this list.

Field: Name

The user designated unique name of an instance of a zone outdoor air unit equipment list.

Field Set (*Component Object Type*, *Component Name*, *Control Node Name*) up to 8

After the identifying name, the list consists of up to 8 pairs of data items.

Field: Component <x> Object Type

This field specifies the keyword for the type of component used.

Field: Component <x> Name

This field is the unique name of the component specified in the previous field. This named object must appear in the IDF.

Note: If any of the components use the autosized option at the component level, input data for zone sizing purposes are required for the proper sizing of the components. Please refer to the Sizing:Zone object for more information.

An example from an IDF:

```
ZoneHVAC:OutdoorAirUnit:EquipmentList,
  Zone5OAUEquip1,           !- Name
  Dehumidifier:Desiccant:NoFans,   !- Component 1 Object Type
  Z5Dessicant,             !- Component 1 Name
  HeatExchanger:AirToAir:FlatPlate, !- Component 2 Object Type
  Zone5A2AHeat Recovery,    !- Component 2 Name
  CoilSystem:Cooling:DX,      !- Component 3 Object Type
  DX Cooling Coil System 5,!- Component 3 Name
  Coil:Heating:Electric,     !- Component 4 Object Type
  Zone5DESHCoil;            !- Component 4 Name
```

ZoneHVAC:WindowAirConditioner

The Window Air Conditioner is a unit of zone equipment made up of other components. Each window air conditioner consists of an outdoor air mixer, a fan, and a direct expansion (DX) cooling coil. These components are described elsewhere in this document. The input for a window air conditioner requires the names of these three pieces of equipment, which are then specified individually elsewhere in the input. The input for a window air conditioner also requires the name of an availability schedule, the maximum unit airflow rate, and the maximum outdoor airflow rate for the unit. The unit is connected to a zone by specifying an air inlet node, which must be the same as a zone exhaust node; and an air outlet node, which must be the same as a zone inlet node (ref. ZoneHVAC:EquipmentConnections).

A supply air fan operating mode schedule must also be specified. The supply air fan operating mode schedule value determines if the supply air fan can run continuously with the DX coil cycling on/off to match the zone cooling demand or the fan and DX coil can cycle on/off together to meet the cooling demand. The placement of the supply air fan, in relation to the DX coil, must also be specified (blow through or draw through). The cooling convergence tolerance is required, which is the tolerance denoting how closely the window air conditioner will meet the cooling load. The tolerance is always relative to the zone load (i.e., the unit will operate to meet the zone load to within the tolerance value times the zone load for each simulation timestep). Finally, the DX cooling coil type must be specified.

Field: Name

A unique user assigned name for an instance of a window air conditioner unit. Any reference to this window air conditioner by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the window air conditioner unit can run during a given hour. A schedule value of 1 indicates that the unit can be on during the hour. A value of 0 denotes that the unit must be off for the hour.

Field: Maximum Supply Air Flow Rate

The maximum volumetric airflow rate through the window air conditioner in cubic meters per second. Since the unit operates by cycling on/off, this is also the design, rated airflow rate of the unit.

Field: Maximum Outdoor Air Flow Rate

If the window air conditioner uses outdoor air, this field specifies the outdoor air volumetric flow rate in cubic meters per second. This flow rate should be less than or equal to the maximum airflow rate. A value of zero specifies no outdoor air. Note that the outdoor airflow rate is fixed: it cannot change during the simulation

Field: Air Inlet Node Name

The name of the HVAC system node (see Node) from which the window air conditioner draws its indoor air. This should be one of the zone exhaust nodes for the zone which the window air conditioner is cooling.

Field: Air Outlet Node Name

The name of the HVAC system node (see Node) to which the window air conditioner sends its outlet air. This should be one of the inlet air nodes for the zone which is being cooled.

Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this window air conditioner unit. The outdoor air mixer component is part of the window air conditioner compound object. The only available outdoor air mixer type is:

OutdoorAir:Mixer

Field: Outdoor Air Mixer Name

The name of an outdoor air mixer component which composes part of the window air conditioner unit. Note that the return air node of the outdoor air mixer should be the same node as the air inlet node of the window air conditioner. In addition, the outdoor air mixer's mixed air node should be the same as the window air conditioner's fan inlet air node (for blow through) or the air conditioner's DX coil inlet node (for draw through)

Field: Supply Air Fan Object Type

This field specifies the type of supply air fan used by window air conditioner. The supply air fan is part of the window air conditioner compound object. The only valid supply air fan types are:

Fan:OnOff
Fan:ConstantVolume

Field: Supply Air Fan Name

The name of a constant volume fan component that composes part of the window air conditioner. Note that the fan's maximum flow rate should be the same as the maximum airflow rate of the window air conditioner. A fan of type Fan:OnOff may be used with either cycling or continuous fan, and a fan of type Fan:ConstantVolume is used only with continuous fan (see Supply Air Fan Operating Mode Schedule field below). The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through) or the DX coil's outlet node (for draw through). The fan's outlet node should be the same as the DX

coil's air inlet node (for blow through) or the window air conditioner's air outlet node (for draw through).

Field: Cooling Coil Object Type

This field specifies the type of cooling coil to be modeled for this window air conditioner. The input requirements for these cooling coil objects are described elsewhere in this document. If the user wants to control the enhanced dehumidification performance of the Heat Exchanger Assisted coil type based on zone air humidity level, then the input file must include a humidistat object (ref. ZoneControl:Humidistat) for the zone being served by this air conditioner and a high humidity set point manager (ref. SetpointManager:SingleZone:Humidity:Maximum) with the high humidity set point placed on the outlet node of the heat exchanger assisted cooling coil. Only allowable coil types are:

```
Coil:Cooling:DX:SingleSpeed  
CoilSystem:Cooling:DX:HeatExchangerAssisted
```

Field: DX Cooling Coil Name

The name of a DX cooling coil component that composes part of the window air conditioner unit. The DX coil air inlet node should be the same as the fan outlet node (for blow through) or the outdoor air mixer's mixed air node (for draw through). The DX coil air outlet node should be the same as the window air conditioner's air outlet node (for blow through) or the fan's inlet node (for draw through).

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation.

Field: Fan Placement

This input field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for "blow through fan". This means that the unit consists of an outdoor air mixer followed by a fan followed by a DX coil. The fan "blows through" the DX coil. The second choice stands for "draw through fan". This means that the unit consists of an outdoor air mixer followed by a DX coil followed by a fan. The fan "draws air through" the coil.

Field: Cooling Convergence Tolerance

This input field defines the convergence tolerance for the unit's cooling output. This field allows the user some control over how closely the air conditioner will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The window air conditioner is controlled by matching its sensible (temperature) cooling output to the zone sensible load (demand). Because the performance of the DX coil is frequently non-linear, the air conditioner model must call the DX coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The cooling convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\left| \frac{Q_{ZoneLoad} - Q_{WindowAirConditioner,out}}{Q_{ZoneLoad}} \right| \leq CoolingConvergenceTolerance$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this window air conditioner or object's fan. If the window air conditioner is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this window air conditioner object should be on or off.

Following is an example input for the cycling window air conditioner, along with its constituent components.

Window AC Total Zone Cooling Rate[W]

This field is the total (sensible and latent) heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Total Zone Cooling Energy[J]

This is the total (sensible and latent) heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the unit, and the timestep.

Window AC Sensible Zone Cooling Rate[W]

This field reports the moist air sensible heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Sensible Zone Cooling Energy[J]

This field reports the moist air sensible heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Latent Zone Cooling Rate[W]

This output is the latent heat extraction rate of the window air conditioner unit from the zone it is serving in Watts. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Latent Zone Cooling Energy[J]

This is the latent heat extraction of the window air conditioner unit from the zone it is serving in Joules over the timestep being reported. This is determined by the outlet and zone conditions and the mass flow rate through the unit.

Window AC Electric Power[W]

This output is the electricity consumption rate of the window air conditioner unit in Watts. The consumption includes electricity used by the compressor and the fans (indoor supply air fan and the condenser fan).

Window AC Electric Consumption[J]

This output is the electricity consumption of the window air conditioner unit in Joules for the time period being reported. The consumption includes electricity used by the compressor and the fans (indoor supply air fan and the condenser fan).

Window AC Fan RunTime Fraction

This is the fraction of the report timestep during which the fan had operated.

Window AC Compressor RunTime Fraction

This is the fraction of the report timestep during which the DX unit compressor had operated.

Window AC Fan Availability Status

This is the availability status of the window air conditioner fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the window air conditioner object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:`* Outputs`). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:PackagedTerminalAirConditioner

The packaged terminal air conditioner (PTAC) is a compound object made up of other components. Each PTAC consists of an outdoor air mixer, direct expansion (DX) cooling coil, heating coil (gas, electric, hot water, or steam) and a supply air fan. While the figure below shows the PTAC with draw through fan placement, blow through fan placement can also be modeled by positioning the supply air fan between the outdoor air mixer and the DX cooling coil. The packaged terminal air conditioner coordinates the operation of these components and is modeled as a type of zone equipment (Ref. ZoneHVAC:EquipmentList and ZoneHVAC:EquipmentConnections).

Figure 98. Schematic of a packaged terminal air conditioner with draw through fan placement

Links to the PTAC's supply air fan, DX cooling coil, heating coil, and outdoor air mixer specifications are provided in the air conditioner's input syntax. Additional inputs include supply and outdoor air flow rates during cooling operation, heating operation, and when neither cooling or heating is required. A description of each input field for the packaged terminal air conditioner compound object is provided below.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a packaged terminal air conditioner. Any reference to this air conditioner by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the air conditioner operates during a given time period. A schedule value equal to 0 denotes that the air conditioner must be off for that time period. A value greater than 0 denotes that the air conditioner is available to operate during that time period. This schedule may be used to completely disable the air conditioner (all of its coils and the supply air fan) as required.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the air conditioner draws its inlet air. This node name must be the name of a zone air exhaust node (Ref. ZoneHVAC:EquipmentConnections).

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the air conditioner sends its outlet air. This node name must be the name of a zone air inlet node (Ref. ZoneHVAC:EquipmentConnections).

Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this PTAC. The outdoor air mixer component is part of the PTAC unit. The only available outdoor air mixer type is:

OutdoorAir:Mixer

Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the PTAC. The return air node of the outdoor air mixer should also be the same node as the air inlet node of the PTAC. Furthermore, the outdoor air mixer's mixed air node should be the same as the PTAC's fan inlet air node (for blow through fan placement) or the PTAC's DX cooling coil inlet node (for draw through fan placement).

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when the heating coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the air conditioner in cubic meters per second when neither cooling nor heating is required (i.e., DX coil and heater are off but the supply air fan operates). This field is only used when the air conditioner's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during cooling operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during cooling operation cannot be greater than the air conditioner's supply air volumetric flow rate during cooling operation.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when the heating coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during heating operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during heating operation cannot be greater than the air conditioner's supply air volumetric flow rate during heating operation.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air flow rate through the air conditioner in cubic meters per second when neither cooling nor heating is required (i.e., cooling and heating coils are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate when no cooling/heating is needed cannot be greater than the air conditioner's supply air volumetric flow rate when no cooling/heating is needed. This field is only used when the air conditioner's supply air fan operating mode schedule specifies continuous fan operation. If the air conditioner's supply air fan operating mode schedule specifies continuous fan operation and the field 'Supply air volumetric flow rate when no cooling or heating is needed' is set to zero

or is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Outdoor air Flow rate during cooling operation] or heating operation [i.e., Outdoor air flow rate during heating operation]) and this field is not used.

Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this PTAC. The only valid choices are **Fan:OnOff** and **Fan:ConstantVolume**. A fan of type Fan:OnOff is used with cycling fan operating mode, and a fan of type Fan:ConstantVolume is used with continuous fan operating mode (see Supply Air Fan Operating Mode Schedule field below). The input requirements for these fan objects are described elsewhere in this document.

Field: Supply Air Fan Name

The name of a constant volume fan component that composes part of the PTAC. Note that the fan's maximum flow rate should be greater than or equal to the maximum supply air flow rate for the PTAC. The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through fan placement) or the heating coil's outlet node (for draw through fan placement). The fan's outlet node should be the same as the DX cooling coil's air inlet node (for blow through fan placement) or the PTAC's air outlet node (for draw through fan placement).

Field: Heating Coil Object Type

This alpha field defines the type of heating coil to be used by this PTAC. The input requirements for this heating coil object are described elsewhere in this document. Allowable heating coil types are:

```
Coil:Heating:Water  
Coil:Heating:Electric  
Coil:Heating:Gas  
Coil:Heating:Steam
```

Field: Heating Coil Name

This alpha field defines the name of the heating coil used by this PTAC, and this name should match the name specified in the corresponding heating coil object.

Field: Cooling Coil Object Type

This alpha field defines the type of DX cooling coil used by this PTAC. The input requirements for these DX cooling coil objects are described elsewhere in this document. Only allowable coil types are:

```
Coil:Cooling:DX:SingleSpeed  
CoilSystem:Cooling:DX:HeatExchangerAssisted
```

Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this PTAC, and this name should match the name specified in the corresponding DX cooling coil object.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for "blow through fan". This means that the unit consists of an outdoor air mixer followed by a fan followed by the DX cooling coil and heating coil. The fan "blows through" the DX cooling coil and the heating coil. The second choice stands for "draw through fan". This means that the unit consists of an outdoor air mixer followed by the DX cooling coil and heating coil with the fan located at the outlet of the PTAC. The fan "draws air through" the DX cooling coil and the heating coil. If this field is left blank, the default is draw through.

Note: the packaged terminal air conditioner's supply air fan, cooling coil and heating coil must be connected according to the configuration shown above (Figure 98) for the draw through fan configuration. The only other valid configuration is with a blow through fan placement, where the fan is located between the outdoor air mixer and the DX cooling coil.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this packaged terminal air conditioner or object's fan. If the packaged terminal air conditioner is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this packaged terminal air conditioner object should be on or off.

As shown in the example below, correct specification of the packaged terminal air conditioner requires the following objects in addition to the compound object itself:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) DX cooling coil (Coil:Cooling:DX:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)
- 3) Heating coil (Coil:Heating:Gas, Coil:Heating:Electric, Coil:Heating:Water, or Coil:Heating:Steam)
- 4) OutdoorAir:Mixer

Packaged Terminal Air Conditioner Total Zone Heating Rate[W]

This output field is the total (enthalpy) heat addition rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Total Zone Heating Energy[J]

This output field is the total (enthalpy) heat addition of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Total Zone Cooling Rate[W]

This output field is the total (enthalpy) heat extraction rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Total Zone Cooling Energy[J]

This output field is the total (enthalpy) heat extraction of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Heating Rate[W]

This output field is the sensible heat addition rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Heating Energy[J]

This output field is the sensible heat addition of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Cooling Rate[W]

This output field reports the moist air sensible heat extraction rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Sensible Zone Cooling Energy[J]

This output field reports the moist air sensible heat extraction of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the air conditioner outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the air conditioner, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Heating Rate[W]

This output field is the latent heat addition (humidification) rate of the packaged terminal air conditioner to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Heating Energy[J]

This output field is the latent heat addition (humidification) of the packaged terminal air conditioner to the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Cooling Rate[W]

This output field is the latent heat extraction (dehumidification) rate of the packaged terminal air conditioner from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Latent Zone Cooling Energy[J]

This output field is the latent heat extraction (dehumidification) of the packaged terminal air conditioner from the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal air conditioner. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Packaged Terminal Air Conditioner Electric Power[W]

This output field is the electricity consumption rate of the packaged terminal air conditioner in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the heating coil (includes electricity consumption rate for electric heating coil or parasitic electricity consumption rate for non-electric coils). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Electric Consumption[J]

This output field is the electricity consumption of the packaged terminal air conditioner in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the heating coil (includes electricity consumption for electric heating coil or parasitic electricity consumption for non-electric coils). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

Packaged Terminal Air Conditioner Fan Part-Load Ratio

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the timestep. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Part-Load Ratio

This output field is the part-load ratio used by the coils (cooling and heating). Part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Air Conditioner Fan Availability Status

This is the availability status of the packaged terminal air conditioner fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the packaged terminal air conditioner object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager.* Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:PackagedTerminalHeatPump

The packaged terminal heat pump (PTHP) is a compound object made up of other components. Each PTHP consists of an outdoor air mixer, direct expansion (DX) cooling coil, DX heating coil, supply air fan, and a supplemental heating coil as shown in the figure below. These individual components are described elsewhere in this document. The packaged terminal heat pump coordinates the operation of these components and is modeled as a type of zone equipment (Ref. ZoneHVAC:EquipmentList and ZoneHVAC:EquipmentConnections).

Figure 99. Schematic of a packaged terminal heat pump (draw through fan placement)

Links to the PTHP's supply air fan, DX coils, supplemental heating coil, and outdoor air mixer specifications are provided in the heat pump's input syntax. Additional inputs include supply and outdoor air flow rates during cooling operation, heating operation, and when neither cooling or heating is required. A description of each input field for the packaged terminal heat pump compound object is provided below.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a packaged terminal heat pump. Any reference to this heat pump by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value greater than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (all of its coils and the supply air fan) as required.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the heat pump draws its inlet air. This node name must be the name of a zone air exhaust node (Ref. ZoneHVAC:EquipmentConnections).

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the heat pump sends its outlet air. This node name must be the name of a zone air inlet node (Ref. ZoneHVAC:EquipmentConnections).

Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this PTHP. The outdoor air mixer component is part of the PTHP compound object. The only available outdoor air mixer type is:

OutdoorAir:Mixer

Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the PTHP. Note that the return air node of the outdoor air mixer should also be the same node as the air inlet node of the PTHP. Furthermore, the outdoor air mixer's mixed air node should be the same as the PTHP's fan inlet air node (for blow through fan placement) or the PTHP's DX cooling coil inlet node (for draw through fan placement).

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during cooling operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during cooling operation cannot be greater than the heat pump's supply air volumetric flow rate during cooling operation.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during heating operation is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate during heating operation cannot be greater than the heat pump's supply air volumetric flow rate during heating operation.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). Values must be greater than or equal to 0, or this field

is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed is fixed; it cannot change during the simulation. In addition, the outdoor air flow rate when no cooling/heating is needed cannot be greater than the heat pump's supply air volumetric flow rate when no cooling/heating is needed. This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and the field 'Supply air volumetric flow rate when no cooling or heating is needed' is set to zero or is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Outdoor air flow rate during cooling operation] or heating operation [i.e., Outdoor air flow rate during heating operation]) and this field is not used.

Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this PTHP. The only valid choices are Fan:OnOff and Fan:ConstantVolume. A fan of type Fan:OnOff may be used with either cycling or continuous fan operating mode, and a fan of type Fan:ConstantVolume is used only with continuous fan operating mode (see Supply Air Fan Operating Mode Schedule field below). The input requirements for these fan objects are described elsewhere in this document.

Field: Supply Air Fan Name

The name of a constant volume fan component that composes part of the PTHP. Note that the fan's maximum flow rate should be greater than or equal to the maximum supply air flow rate for the PTHP. The fan's inlet node should be the same as the outdoor air mixer's mixed air node (for blow through fan placement) or the DX heating coil's outlet node (for draw through fan placement). The fan's outlet node should be the same as the DX cooling coil's air inlet node (for blow through fan placement) or the supplemental heater's air inlet node (for draw through fan placement).

Field: Heating Coil Object Type

This alpha field defines the type of DX heating coil to be used by this PTHP. The only valid choice is **Coil:Heating:DX:SingleSpeed**. The input requirements for this DX heating coil object are described elsewhere in this document.

Field: Heating Coil Name

This alpha field defines the name of the DX heating coil used by this PTHP, and this name should match the name specified in the corresponding DX heating coil object.

Field: Heating Convergence Tolerance

This numeric field defines the convergence tolerance for the unit's heating output. This field allows the user some control over how closely the heat pump will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The heat pump is controlled by matching its sensible (temperature) heating output to the zone sensible load (demand). Because the performance of the DX heating coil is frequently non-linear, the heat pump model must call the DX heating coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The heating convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|(Q_{ZoneLoad} - Q_{HeatPump,out})|}{Q_{ZoneLoad}} \leq HeatingConvergenceTolerance$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor dry-bulb temperature in degrees Celsius for PTHP compressor operation. The compressor will not operate (for DX heating or DX cooling) when outdoor dry-bulb temperatures fall below this value. The minimum value must be greater than or equal to -20 °C. If this field is left blank, the default value is -8°C. This temperature should match the minimum compressor operating temperature specified for the heat pump's DX heating coil (if they don't match, the highest of the two temperatures will be the cut-off temperature for compressor operation).

Field: Cooling Coil Object Type

This alpha field defines the type of DX cooling coil used by this PTHP. The input requirements for these DX cooling coil objects are described elsewhere in this document. Only allowable coil types are:

Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted

Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this PTHP, and this name should match the name specified in the corresponding DX cooling coil object.

Field: Cooling Convergence Tolerance

This numeric field defines the convergence tolerance for the unit's cooling output. This field allows the user some control over how closely the heat pump will control the air-side conditions. The relative size of this parameter relates directly to the closeness of the control. A very small value in this field will result in tight control and will probably result in larger numbers of iterations. A large value in this field will result in looser controls and could result in unsatisfactory fluctuations in zone air temperature. Initial experience with this parameter lends to the recommendation of using 0.001 as the starting point.

The heat pump is controlled by matching its sensible (temperature) cooling output to the zone sensible load (demand). Because the performance of the DX cooling coil is frequently non-linear, the heat pump model must call the DX cooling coil model several times (iterate) to determine the proper run time fraction to meet the zone load. The cooling convergence tolerance is the error tolerance used to terminate the iteration procedure when the following equation is satisfied:

$$\frac{|(Q_{ZoneLoad} - Q_{HeatPump,out})|}{Q_{ZoneLoad}} \leq CoolingConvergenceTolerance$$

The maximum number of iterations is limited, with a warning message generated if the above equation is not satisfied within the maximum number of iterations.

Field: Supplemental Heating Coil Object Type

This alpha field defines the type of supplemental heating coil to be used by this PTHP. The input requirements for these heating coil objects are described elsewhere in this document. The hot water and steam heating coils require specifying plant loop, branches, and connector

objects to support the heating coils, and are placed on the demand side of the plantloop. Only allowable coil types are:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Water
Coil:Heating:Steam

Field: Supplemental Heating Coil Name

This alpha field defines the name of the supplemental heating coil used by this PTHP, and this name should match the name specified in the corresponding heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum supply air temperature in degrees Celsius exiting the heat pump supplemental heater coil. The supplemental heater will be controlled so that its supply air temperature does not exceed this value. This field is autosizable.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the maximum outdoor dry-bulb temperature in degrees Celsius for PTHP supplemental heater operation. The supplemental heater will not operate when the outdoor dry-bulb temperature is above this value. The maximum value must be less than or equal to 21°C. If this field is left blank, the default value is 21°C.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of an outdoor air mixer followed by a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of an outdoor air mixer followed by the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is draw through.

Note: the packaged terminal heat pump's supply air fan, cooling coil, heating coil and supplementary heating coil must be connected according to the configuration shown above (Figure 99) for the draw through fan configuration. The only other valid configuration is with a blow through fan placement, where the fan is located between the outdoor air mixer and the DX cooling coil.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation.

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this packaged terminal heat pump or object's fan. If the packaged terminal heat pump is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this packaged terminal heat pump object should be on or off.

As shown in the example below, correct specification of the packaged terminal heat pump requires the following objects in addition to the compound object itself:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) DX cooling coil (Coil:Cooling:DX:SingleSpeed or CoilSystem:Cooling:DX:HeatExchangerAssisted)
- 3) DX heating coil (Coil:Heating:DX:SingleSpeed)
- 4) Supplemental heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 5) OutdoorAir:Mixer

Packaged Terminal Heat Pump Total Zone Heating Rate[W]

This output field is the total (enthalpy) heat addition rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Total Zone Heating Energy[J]

This output field is the total (enthalpy) heat addition of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Total Zone Cooling Rate[W]

This output field is the total (enthalpy) heat extraction rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Total Zone Cooling Energy[J]

This output field is the total (enthalpy) heat extraction of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Heating Rate[W]

This output field is the sensible heat addition rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Heating Energy[J]

This output field is the sensible heat addition of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Cooling Rate[W]

This output field reports the moist air sensible heat extraction rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Sensible Zone Cooling Energy[J]

This output field reports the moist air sensible heat extraction of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Heating Rate[W]

This output field is the latent heat addition (humidification) rate of the packaged terminal heat pump to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Heating Energy[J]

This output field is the latent heat addition (humidification) of the packaged terminal heat pump to the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Cooling Rate[W]

This output field is the latent heat extraction (dehumidification) rate of the packaged terminal heat pump from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Packaged Terminal Heat Pump Latent Zone Cooling Energy[J]

This output field is the latent heat extraction (dehumidification) of the packaged terminal heat pump from the zone it is serving in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the packaged terminal heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Packaged Terminal Heat Pump Electric Power[W]

This output field is the electricity consumption rate of the packaged terminal heat pump in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Heat Pump Electric Consumption[J]

This output field is the electricity consumption of the packaged terminal heat pump in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

Packaged Terminal Heat Pump Fan Part-Load Ratio

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the timestep. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Heat Pump Compressor Part-Load Ratio

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). Compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Packaged Terminal Heat Pump Fan Availability Status

This is the availability status of the packaged terminal heat pump fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the packaged terminal heat pump object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:`*` Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:RefrigerationChillerSet

The ZoneHVAC:RefrigerationChillerSet object works in conjunction with one or multiple air chillers, compressor racks, refrigeration systems, or refrigeration secondary system objects (Ref. Refrigeration:AirChiller Refrigeration:CompressorRack, Refrigeration:System, or Refrigeration:SecondarySystem) to simulate the performance of a group of air chillers cooling a single zone. The chiller set model passes information about the zone conditions to determine the performance of individual chiller coils within the set, thus providing the sensible and latent heat exchange with the zone environment.

The refrigeration chiller set object inputs include a name, an availability schedule name, the name of the zone cooled by the chiller set, the air inlet node name, the air outlet node name, and an extensible list of air chiller names (Ref. Refrigeration:AirChiller).

Field: Name

A unique user-assigned name for an instance of a refrigeration chiller. Any reference to this refrigeration chiller by another object (may be listed in a Refrigeration:CaseAndWalkInList, Refrigeration:System, Refrigeration:SecondarySystem, or Refrigeration:CompressorRack) will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigeration chiller can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the refrigeration chiller will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the refrigeration chiller will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, refrigeration chillers require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the default schedule has a value of 1 for all time periods.

Field: Zone Name

A unique user-assigned name for the zone cooled by this refrigeration chiller. This zone must represent a conditioned space, that is, it must appear in a ZoneHVAC:EquipmentConnections object.

Field: Air Inlet Node Name

Not used, reserved for future use. Current version exchanges energy directly with the zone, external of any air system. (Future: The name of the zone exhaust node (see Node) from which the refrigeration chiller draws its indoor air. This should be one of the zone exhaust nodes for the zone cooled by the chiller set.)

Field: Air Outlet Node Name

Not used, reserved for future use. Current version exchanges energy directly with the zone, external of any air system. (Future: The name of the node where the chiller coil sends its outlet air, which must be one of the inlet air nodes for the zone which is being cooled.)

Field: Air Chiller #1 Name

The name of the first air chiller that will be used to meet the zone cooling load.

Field: Air Chiller #2 Name

The name of the second air chiller that will be used to meet the zone cooling load.

Field: Air Chiller #3 Name

The name of the third air chiller that will be used to meet the zone cooling load.

Field: Air Chiller #n Name (Extensible list, 20 provided in the IDD)

The name of the nth air chiller that will be used to meet the zone cooling load.

The following is an example input for a refrigeration chiller set.

```
ZoneHVAC:RefrigerationChillerSet,
SubFreezerChillerSet ,      !- Name
,                         !- Availability Schedule Name
SubFreezer,                !- Zone Name
NODE_142,                  !- Air Inlet Node Name
NODE_141,                  !- Air Outlet Node Name
SubFreezerAirChiller_1,     !- Air Chiller #1 Name
SubFreezerAirChiller_2,     !- Air Chiller #2 Name
SubFreezerAirChiller_3;     !- Air Chiller #3 Name
```

There are no outputs variables for a ZoneHVAC:RefrigerationChillerSet. Outputs for the refrigeration impact on any zone are listed in the Group:Refrigeration.

ZoneHVAC:WaterToAirHeatPump

The zone water-to-air heat pump is a compound component consisting of a fan, water-to-air cooling and heating coils, and a supplemental heating coil. Links to the fan, WaterToAirHeatPump cooling coil, WaterToAirHeatPump heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. The heat pump switches between cooling and heating depending on the zone's demand. The load side (air) of the zone water-to-air heat pump consists of an On/Off fan component, a WaterToAirHeatPump cooling coil component, a WaterToAirHeatPump heating coil component, and a Gas or Electric supplemental heating coil component. The source side (water) of the heat pump is connected to a condenser loop with a heat exchanger (ground heat exchanger or other type) or a plant loop with a heating source such as a boiler and a cooling source such as a chiller or cooling tower. The diagram below shows the setup and connection of the heat pump for the source side and load side for a ground heat exchanger configuration. Note that on the load side, the WaterToAirHeatPump cooling coil must always be placed before the WaterToAirHeatPump heating coil.

For this zone heat pump, there is one type of WaterToAirHeatPump coil model allowed:

Coil:Cooling:WaterToAirHeatPump:EquationFit
Coil:Heating:WaterToAirHeatPump:EquationFit

Load Side (air)

Figure 100. Zone Water to Air Heat Pump Schematic for a DrawThrough Configuration with Ground Heat Exchanger

Field: Name

This alpha field contains the identifying name for the zone system heat pump.

Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air. This node must be a zone exhaust node as specified in a ZoneHVAC:EquipmentConnections object.

Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air. This node must be a zone inlet node as specified in a ZoneHVAC:EquipmentConnections object.

Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this WaterToAirHeatPump unit. The outdoor air mixer component is part of the WaterToAirHeatPump compound object. The only available outdoor air mixer type is:

OutdoorAir:Mixer

Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component which composes part of the zone WaterToAirHeatPump. The return air stream node of the outdoor air mixer should also be the same node as the air inlet node of the WaterToAirHeatPump. Furthermore, the outdoor air mixer's mixed air node should be the same as the WaterToAirHeatPump's fan inlet air node (for blow through fan placement) or the WaterToAirHeatPump's cooling coil inlet node (for draw through fan placement).

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the cooling or heating coil was last operating (for cooling operation or heating operation).

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outside air flow rate during cooling operation is fixed; it cannot change during the simulation. In addition, the outside air flow rate during cooling operation cannot be greater than the heat pump's supply air volumetric flow rate during cooling operation.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outside air flow rate during heating operation is fixed; it cannot change during the simulation. In addition, the outside air flow rate during heating operation cannot be greater than the heat pump's supply air volumetric flow rate during heating operation.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air flow rate through the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outside air flow rate when no cooling/heating is needed is fixed; it cannot change during the simulation. In addition, the outside air flow rate when no cooling/heating is needed cannot be greater than the heat pump's supply air volumetric flow rate when no cooling/heating is needed. This field is only used when the heat pump's supply air fan operating mode schedule specifies continuous fan operation. If the heat pump's supply air fan operating mode schedule specifies continuous fan operation and the field 'Supply air volumetric flow rate when no cooling or heating is needed' is set to zero or is left blank, then the model assumes that the outside air flow rate when no cooling/heating is needed is equal to the outside air flow rate when the cooling or heating coil was last operating (for cooling operation [i.e., Outside air volumetric flow rate during cooling operation] or heating operation [i.e., Outside air volumetric flow rate during heating operation]) and this field is not used.

Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified in the heat pump. Fan type must be Fan:OnOff.

Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. The only valid type is Coil:Heating:WaterToAirHeatPump:EquationFit.

Field: Heating Coil Name

This alpha field contains the identifying name given to the WaterToAirHeatPump heating coil, and should match the name specified in the corresponding WaterToAirHeatPump heating coil object.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. The only valid type is Coil:Cooling:WaterToAirHeatPump:EquationFit.

Field: Cooling Coil Name

This alpha field contains the identifying name given to the WaterToAirHeatPump cooling coil, and should match the name specified in the corresponding WaterToAirHeatPump cooling coil object.

Field: Maximum Cycling Rate

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Field: Heat Pump Time Constant

This numeric field contains the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Field: Fraction of On-Cycle Power Use

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	0.01
Good	0.01
Poor	0.03

Field: Heat Pump Fan Delay Time

This numeric field contains the time delay in seconds for the heat pump supply air fan to shut off after compressor cycle off. This value can be obtained from the manufacturer or the heat pump catalog. Suggested value is 60 seconds. This value is disregarded at times when the WaterToAirHeatPump's fan operating mode schedule value is greater than 0 (i.e., continuous fan mode).

Field: Supplemental Heating Coil Object Type

This is the object type of the supplemental heating coil. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The valid choices are:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Water
Coil:Heating:Steam

Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the supplemental heating coil, and should match the name specified in the corresponding supplemental heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil in degrees Celsius.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature in degrees Celsius above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Outdoor Dry-Bulb Temperature Sensor Node Name

This alpha field specifies the name of the outdoor node which controls the operation of the supplemental heating coil. If this field is left blank, the outdoor temperature is based solely on the weather data. If this field is not blank, the node name specified must also be listed in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an OutdoorAir:NodeList object where the outdoor temperature is taken directly from the weather data.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply fan is between the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation.

As shown in the example below, correct specifications of the WatertoAirHeatPump requires specification of the following objects in addition to the ZoneHVAC:WaterToAirHeatPump object:

- On/Off fan
- WatertoAirHeatPump cooling coil (EquationFit only)
- WatertoAirHeatPump heating coil (EquationFit only)
- Supplementary heating coil
- Outdoor air mixer
- Condenser loop or plant loop demand branches

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this WatertoAirHeatPump or object's fan. If the WatertoAirHeatPump is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this WatertoAirHeatPump object should be on or off.

Zone Water Source Heat Pump Total Zone Heating Rate[W]

This output field is the total (enthalpy) heat addition rate of the Water to Air Heat Pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy addition only) are averaged for the time step being reported.

Zone Water Source Heat Pump Total Zone Heating Energy[J]

This output field is the total (enthalpy) heat addition of the Water to Air Heat Pump to the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy addition only) are summed for the time step being reported.

Zone Water Source Heat Pump Total Zone Cooling Rate[W]

This output field is the total (enthalpy) heat extraction rate of the Water to Air Heat Pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy extraction only) are averaged for the time step being reported.

Zone Water Source Heat Pump Total Zone Cooling Energy[J]

This output field is the total (enthalpy) heat extraction of the Water to Air Heat Pump from the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (enthalpy extraction only) are summed for the time step being reported.

Zone Water Source Heat Pump Sensible Zone Heating Rate[W]

This output field is the sensible heat addition rate of the Water to Air Heat Pump to the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (heating only) are averaged for the time step being reported.

Zone Water Source Heat Pump Sensible Zone Heating Energy[J]

This output field is the sensible heat addition of the Water to Air Heat Pump to the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (heating only) are summed for the time step being reported.

Zone Water Source Heat Pump Sensible Zone Cooling Rate[W]

This output field reports the moist air sensible heat extraction rate of the Water to Air Heat Pump from the zone it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system time step being simulated, and the results (cooling only) are averaged for the time step being reported.

Zone Water Source Heat Pump Sensible Zone Cooling Energy[J]

This output field reports the moist air sensible heat extraction of the Water to Air Heat Pump from the zone it is serving in Joules over the time step being reported. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, the air mass flow rate through the heat pump, and the HVAC simulation time step. This value is calculated for each HVAC system time step being simulated, and the results (cooling only) are summed for the time step being reported.

Zone Water Source Heat Pump Latent Zone Heating Rate[W]

This output field is the latent heat addition (humidification) rate of the Water to Air Heat Pump to the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat addition only) are averaged for the time step being reported.

Zone Water Source Heat Pump Latent Zone Heating Energy[J]

This output field is the latent heat addition (humidification) of the Water to Air Heat Pump to the zone it is serving in Joules over the time step being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat addition only) are summed for the time step being reported.

Zone Water Source Heat Pump Latent Zone Cooling Rate[W]

This output field is the latent heat extraction (dehumidification) rate of the Water to Air Heat Pump from the zone it is serving in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat extraction only) are averaged for the time step being reported.

Zone Water Source Heat Pump Latent Zone Cooling Energy[J]

This output field is the latent heat extraction (dehumidification) of the Water to Air Heat Pump from the zone it is serving in Joules over the time step being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the WaterToAirHP heat pump. This value is calculated for each HVAC system time step being simulated, and the results (latent heat extraction only) are summed for the time step being reported.

Zone Water Source Heat Pump Electric Power[W]

This output field is the electricity consumption rate of the Water to Air Heat Pump in Watts. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Zone Water Source Heat Pump Electric Consumption[J]

This output field is the electricity consumption of the Water to Air Heat Pump in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), fans (indoor supply air fan and the condenser fan), and the supplemental heating coil (if electric). This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported.

Zone Water Source Heat Pump Fan Part-Load Ratio

This output field is the part-load ratio of the fan. The fan part-load ratio is defined as the average supply air mass flow rate divided by the maximum supply air mass flow rate. The

maximum supply air mass flow rate depends on whether heating, cooling, or no heating or cooling is required during the time step. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Zone Water Source Heat Pump Compressor Part-Load Ratio

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). Compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Zone Water Source Heat Pump Fan Availability Status

This is the availability status of the zone water source heat pump fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the zone water source heat pump object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:^{*} Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section ‘Group – System Availability Managers’. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:Dehumidifier:DX

This object can be used for modeling conventional mechanical dehumidifiers. These systems use a direct expansion (DX) cooling coil to cool and dehumidify an airstream. Heat from the DX system’s condenser section is rejected into the cool/dehumidified airstream, resulting in warm dry air being supplied from the unit. In EnergyPlus, this object is modeled as a type of zone equipment (ref. ZoneHVAC:EquipmentList and ZoneHVAC:EquipmentConnections).

Figure 101. Schematic of a mechanical dehumidifier

The model has inputs for water removal, energy factor and air flow rate at rated conditions (26.7°C, 60% RH). Curve objects must be specified to describe performance at off-rated conditions. A part-load cycling curve input must also be specified to account for inefficiencies due to cycling. Other inputs including minimum and maximum operating temperatures for

dehumidifier operation, off-cycle parasitic load, and an input to direct the removed water to a storage tank.

The model assumes that this equipment dehumidifies and heats the air. If used in tandem with another system that cools and dehumidifies the zone air, then the zone dehumidifier should be specified as the lowest cooling priority in the ZoneHVAC:EquipmentList object for best control of zone temperature and humidity levels (e.g., if there are 3 pieces of equipment in ZoneHVAC:EquipmentList, then the zone dehumidifier should have Cooling Priority = 3). With this zone equipment prioritization, the other cooling and dehumidification system would operate first to meet the temperature setpoint (and possibly meet the high humidity setpoint as well). If additional dehumidification is needed, then the zone dehumidifier would operate. The sensible heat generated by the dehumidifier is carried over to the zone air heat balance for the next HVAC time step.

Field: Name

A unique user-assigned name for an instance of a zone DX dehumidifier unit. Any reference to this dehumidifier by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the dehumidifier operates during a given time period. A schedule value equal to 0 denotes that the dehumidifier will not operate for that time period. A value greater than 0 denotes that the dehumidifier is available to operate during that time period.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the dehumidifier draws its inlet air. This node name must be the name of a zone air exhaust node (ref. ZoneHVAC:EquipmentConnections).

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the dehumidifier sends its outlet air. This node name must be the name of a zone air inlet node (ref. ZoneHVAC:EquipmentConnections).

Field: Rated Water Removal

This numeric input is the full load water removal rate, in liters per day, at rated conditions (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field “Rated Air Flow Rate” below). This is a required input field and the entered value must be greater than zero.

Field: Rated Energy Factor

This numeric input is the energy factor (liters of water removed per kWh of electricity consumed) at rated conditions (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field “Rated Air Flow Rate” below). This is a required input field and the entered value must be greater than zero.

Field: Rated Air Flow Rate

This numeric input is the volumetric air flow rate through the dehumidifier, in m³ per second, at rated conditions (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity). This is a required input field and the entered value must be greater than zero.

Field: Water Removal Curve Name

This alpha field defines the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of water removal as a function of the dry-bulb temperature (°C) and relative humidity (%) of the air entering the dehumidifier. The output of this curve is multiplied by the Rated Water Removal to give the water removal of the

dehumidifier at specific operating conditions (i.e., at temperatures and relative humidity levels different from the rating point conditions). The curve should be normalized to have the value of 1.0 at the rating point (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field “Rated Air Flow Rate” above).

Field: Energy Factor Curve Name

This alpha field defines the name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy factor as a function of the dry-bulb temperature (°C) and relative humidity (%) of the air entering the dehumidifier. The output of this curve is multiplied by the Rated Energy Factor to give the energy factor of the dehumidifier at specific operating conditions (i.e., at temperatures and relative humidity levels different from the rating point conditions). The curve should be normalized to have the value of 1.0 at the rating point (air entering the dehumidifier at 26.7°C [80°F] dry-bulb and 60% relative humidity, and air flow rate as defined by field “Rated Air Flow Rate” above).

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of electrical power input to the dehumidifier as a function of the part load ratio (PLR, defined as the water removal load to be met (kg/s) divided by the dehumidifier’s water removal rate (kg/s) at the current operating conditions). The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the dehumidifier runs continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$0.7 \leq PLF \leq 1.0 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the dehumidifier is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the dehumidifier is set to 1.0.

Mechanical dehumidifier typically have long runtimes with minimal compressor cycling. So, a typical part load fraction correlation might be:

$$PLF = 0.95 + 0.05(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Minimum Dry-Bulb Temperature for Dehumidifier Operation

This numeric field defines the minimum inlet air dry-bulb temperature for dehumidifier operation. The dehumidifier will not operate if the inlet air temperature is below this value. This input value must be less than the Maximum Dry-Bulb Temperature for Dehumidifier Operation, and the default value is 10°C.

Field: Maximum Dry-Bulb Temperature for Dehumidifier Operation

This numeric field defines the maximum inlet air dry-bulb temperature for dehumidifier operation. The dehumidifier will not operate if the inlet air temperature is above this value. This input value must be greater than the Minimum Dry-Bulb Temperature for Dehumidifier Operation, and the default value is 35°C.

Field: Off-Cycle Parasitic Electric Load

This numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the dehumidifier. This parasitic electric load is consumed whenever the dehumidifier is available

to operate, but is not operating. The model assumed that this parasitic power contributes to heating the zone air (i.e., affects the zone air heat balance). The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to specify where condensate from the dehumidifier is collected. If blank or omitted, then any water (condensate) removed is discarded. Enter the name of a Water Storage Tank (ref. WaterUse:Storage) object defined elsewhere and the condensate will then be collected in that tank.

Following is an example input for a zone DX dehumidifier object. A ZoneControl:Humidistat object must also be specified for the zone to which the dehumidifier is connected (connect via a zone air exhaust node and a zone air inlet node, ref. ZoneHVAC:EquipmentConnections).

Zone Dehumidifier Sensible Heating Rate [W]

This output field is the sensible heating rate output of the dehumidifier in Watts. This is determined by the water removal rate, enthalpy of water evaporation, and the zone dehumidifier electric power. To reduce simulation time, this heating is carried over to the zone air heat balance for the next HVAC time step (i.e., it is reported here for the current time step but actually impacts the zone air heat balance on the following HVAC time step). This value is

calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

Zone Dehumidifier Sensible Heating Energy [J]

This output field is the sensible heating output of the dehumidifier in Joules over the timestep being reported. This is determined by the water removal rate, enthalpy of water evaporation, and the zone dehumidifier electric power. To reduce simulation time, this heating is carried over to the zone air heat balance for the next HVAC time step (i.e., it is reported here for the current time step but actually impacts the zone air heat balance on the following HVAC time step). This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported.

Zone Dehumidifier Water Removal Rate [kg/s]

This output field is the water removal rate by the dehumidifier in kg/s. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

Zone Dehumidifier Water Removed [kg]

This output field is the water removed by the dehumidifier in kg. This value is calculated for each HVAC system timestep, and the results are summed for the timestep being reported.

Zone Dehumidifier Electric Power [W]

Zone Dehumidifier Electric Consumption [J]

These outputs are the electric power and electric consumption of the dehumidifier for the time period being reported. They include all electricity used by the dehumidifier (including off-cycle electric parasitics). These values are calculated for each HVAC system timestep, and the results are averaged (power) or summed (consumption) for the timestep being reported. The electric consumption output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Zone Dehumidifier Off-Cycle Parasitic Electric Power [W]

Zone Dehumidifier Off-Cycle Parasitic Electric Consumption [J]

These outputs are the parasitic electric power and electric consumption for controls or other electrical devices associated with the dehumidifier. This parasitic electric load is consumed whenever the dehumidifier is available to operate, but is not operating. The model assumes that this parasitic power contributes to heating the zone air (i.e., affects the zone air heat balance). These outputs values are included in the Zone Dehumidifier Electric Power and Zone Dehumidifier Electric Consumption output variables.

Zone Dehumidifier Part-Load Ratio [-]

This output field is the part-load ratio for the dehumidifier. Part-load ratio is defined as the water removal load to be met (kg/s) divided by the dehumidifier's water removal rate (kg/s) at the current operating conditions. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

Zone Dehumidifier Runtime Fraction [-]

This output field is the runtime fraction for the dehumidifier. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

Zone Dehumidifier Outlet Air Temperature [C]

This output field is dry-bulb temperature of the air leaving the dehumidifier in Celsius. This value represents the dry-bulb temperature of the air leaving the dehumidifier when it is operating. For periods when the dehumidifier is not operating, the outlet air temperature is set

equal to the inlet air temperature. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

Zone Dehumidifier Condensate Volumetric Flow Rate [m³/s]

Zone Dehumidifier Condensate Volume [m³]

These outputs are the rate and volume of water removed as condensate by the dehumidifier. These reports only appear if a water storage tank is named in the input object. The condensate volume output is also added to a report meter with Resource Type = OnSiteWater, End Use Key = Condensate, Group Key = System (ref. Report Meter).

ZoneHVAC:EnergyRecoveryVentilator

The ZoneHVAC:EnergyRecoveryVentilator - stand alone energy recovery ventilator (ERV) is a single-zone HVAC component used for exhaust air heat recovery (Figure 102). This compound object consists of 3 required components: a generic air-to-air heat exchanger (see object Heat Exchanger:Air to Air:Generic), a supply air fan, and an exhaust air fan (see object Fan:OnOff).

An optional controller (see object ZoneHVAC:EnergyRecoveryVentilator:Controller) may be used to simulate economizer (free cooling) operation, modify air flow rates based on high indoor humidity, or simulate a “push-button” type economizer controller.

Figure 102. ZoneHVAC:EnergyRecoveryVentilator compound object Schematic

This compound object models the basic operation of supply and exhaust air fans and an air-to-air heat exchanger. The stand alone ERV operates whenever the unit is scheduled to be available (Availability schedule). The stand alone ERV object can be used in conjunction with an economizer feature whereby heat exchange is suspended whenever free cooling is available (i.e., air flow is fully bypassed around a fixed-plate heat exchanger or the rotation of a rotary heat exchanger is stopped). The economizer feature may also be activated based on a time-of-day schedule. Heat exchange is also suspended when air flow rates through the heat exchanger are modified in response to a zone humidistat. When an economizer is used in conjunction with high humidity control, high humidity control has the priority.

To model a stand alone ERV connected to a single zone, the input data file should include the following objects:

- ZoneHVAC:EnergyRecoveryVentilator
- HeatExchanger:AirToAir:SensibleAndLatent
- Fan:OnOff (supply air)
- Fan:OnOff (exhaust air)
- ZoneHVAC:EnergyRecoveryVentilator:Controller (if economizer [free cooling] mode or high humidity control operation is desired)
- ZoneControl:Humidistat (required for high humidity control option)
- SetpointManager:Scheduled (if supply air outlet temperature control is used, Ref. Heat Exchanger:Air to Air:Generic for additional guidance)
- ZoneHVAC:EquipmentConnections
- ZoneHVAC:EquipmentList
- OutdoorAir:NodeList

A description of each input field for this compound object is provided below.

Field: Name

A unique user-assigned name for the stand alone ERV unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the unit can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can operate during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit will not operate.

Field: Heat Exchanger Name

The user-assigned name corresponding to the air-to-air heat exchanger used in this compound object. The only allowable type is:.

HeatExchanger:AirToAir:SensibleAndLatent
--

Field: Supply Air Flow Rate

The supply air flow rate through the ERV unit in cubic meters per second at standard temperature and pressure (dry air at 20° C drybulb). The program uses local barometric pressure to account for altitude using the equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)^{5.2559}$$

where p=pressure in Pa and Z=altitude in m

Note that this flow rate must be within the valid air flow range for the heat exchanger (ref: HeatExchanger:AirToAir:SensibleAndLatent in the Engineering Document). In addition, this flow rate must be less than or equal to the supply fan air flow rate (Fan:OnOff). If the supply air flow rate is less than the exhaust air flow rate, the zone infiltration (ref: ZoneInfiltration) should be specified accordingly (the infiltration induced by imbalanced air flows is not accounted for automatically). The ERV supply air flow rate may also be autosized using the ventilation rate per floor area and/or ventilation rate per occupant fields below. When autosizing, the heat exchanger and fan air flow rates should also be autosized.

Note: The supply air inlet node specified in the generic heat exchanger object must be an outdoor air node (ref: OutdoorAir:Node and OutdoorAir:NodeList). The supply air outlet node specified in the generic heat exchanger object must be a zone air inlet node (ref: ZoneHVAC:EquipmentConnections).

Field: Exhaust Air Flow Rate

The exhaust air flow rate through the ERV unit in cubic meters per second at standard temperature and pressure (dry air at 20° C drybulb). The program uses local barometric pressure to account for altitude using the equation for "standard atmospheric" pressure on p 6.1 of the ASHRAE 1997 HOF (SI edition) to initialize the air systems being simulated.

$$p=101325*(1-2.25577E-05*Z)^{**}5.2559$$

where p=pressure in Pa and Z=altitude in m

Note that this flow rate must be within the valid air flow range for the heat exchanger (ref: HeatExchanger:AirToAir:SensibleAndLatent in the Engineering Document). In addition, this flow rate must be less than or equal to the exhaust fan air flow rate (Fan:OnOff). If the exhaust air flow rate is greater than the supply air flow rate, the zone infiltration (ref: ZoneInfiltration) should be specified accordingly (the infiltration induced by imbalanced air flows is not accounted for automatically). The ERV exhaust air flow rate may also be autosized using the ventilation rate per floor area and/or ventilation rate per occupant fields below. When autosizing, the heat exchanger and fan air flow rates should also be autosized.

Note: The exhaust air inlet node specified in the generic heat exchanger object must be a zone air exhaust node (ref: ZoneHVAC:EquipmentConnections).

Field: Supply Air Fan Name

The name of the supply air fan used in this object. Fan type must be Fan:OnOff.

Field: Exhaust Air Fan Name

The name of the exhaust air fan used in this object. Fan type must be Fan:OnOff.

Field: Controller Name

This optional field specifies the name of the controller used by this compound component if economizer (free cooling) mode or high humidity control operation is desired. Controller type must be ZoneHVAC:EnergyRecoveryVentilator:Controller.

Field: Ventilation Rate per Unit Floor Area

This optional numeric field defines the ventilation rate per unit floor area in cubic meters per second per square meter. This field is only used when the supply and exhaust air flow rates are autosized.

Field: Ventilation Rate per Occupant

This optional numeric field defines the ventilation rate per occupant in cubic meters per second per occupant. This field is only used when the supply and exhaust air flow rates are autosized.

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this Stand Alone ERV object's fan. If the Stand Alone ERV is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then

the availability managers in the list determine when and if the fan of this Stand Alone ERV object should be on or off.

Following is an example input for this compound object and associated objects that may be defined:

Stand Alone ERV Electric Power [W]

This output field is the electric consumption rate of the stand alone energy recovery ventilator in Watts. This rate includes the electric consumption by the supply air fan, exhaust air fan and the generic air-to-air heat exchanger.

Stand Alone ERV Electric Consumption [J]

This output field is the electric consumption of the stand alone energy recovery ventilator in Joules for the timestep being reported. This value includes the electric consumption by the supply air fan, exhaust air fan and the generic air-to-air heat exchanger.

Stand Alone ERV Zone Total Cooling Rate [W]

This output field is the total (enthalpy) heat extraction rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Stand Alone ERV Zone Total Cooling Energy [J]

This output field is the total (enthalpy) heat extraction of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Stand Alone ERV Zone Total Heating Rate [W]

This output field is the total (enthalpy) heat addition rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Stand Alone ERV Zone Total Heating Energy [J]

This output field is the total (enthalpy) heat addition of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Stand Alone ERV Zone Sensible Cooling Rate [W]

This output is the moist air sensible heat extraction rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Stand Alone ERV Zone Sensible Cooling Energy [J]

This output is the moist air sensible heat extraction of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Stand Alone ERV Zone Sensible Heating Rate [W]

This output is the sensible heat addition rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated using the supply air outlet mass flow rate, and the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Stand Alone ERV Zone Sensible Heating Energy [J]

This output is the sensible heat addition of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated using the supply air outlet mass flow rate, the enthalpy difference of the supply outlet and exhaust inlet air streams at a constant humidity ratio, and the HVAC system timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Stand Alone ERV Zone Latent Cooling Rate [W]

This output is the latent heat extraction (dehumidification) rate of the stand alone energy recovery ventilator from the zone in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Stand Alone ERV Zone Latent Cooling Energy [J]

This output is the latent heat extraction (dehumidification) of the stand alone energy recovery ventilator from the zone in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Stand Alone ERV Zone Latent Heating Rate [W]

This output is the latent heat addition (humidification) rate of the stand alone energy recovery ventilator to the zone in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Stand Alone ERV Zone Latent Heating Energy [J]

This output is the latent heat addition (humidification) of the stand alone energy recovery ventilator to the zone in Joules over the timestep being reported. This value is calculated as the difference between the total energy delivered to the zone and the sensible energy delivered to the zone by the stand alone ERV. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Stand Alone ERV Supply Fan Availability Status []

This is the availability status of the Stand Alone ERV fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the Stand Alone ERV object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:^{*} Outputs). For multiple availability managers in an Availability Manager Assignment List (with or without Hybrid Ventilation Manager), rules to determine fan availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the "detailed" reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:TerminalUnit:VariableRefrigerantFlow

Zone terminal units with variable refrigerant flow DX coils are used exclusively with variable refrigerant flow (VRF) air conditioning systems (Ref. AirConditioner:VariableRefrigerantFlow). The zone terminal units are connected to a zone using the inlet and exhaust node names specified in a ZoneHVAC:EquipmentConnections object. The zone exhaust node has the same name as the terminal unit air inlet node. The zone inlet node has the same name as the terminal unit air outlet node. The zone terminal unit is also listed in a zone's equipment list and will typically be the first equipment operating for both cooling and heating (i.e., Sequence = 1 in the ZoneHVAC:EquipmentList). Other ZoneHVAC equipment may be used in the same zone and should be sequenced to operate after the zone terminal units (i.e., sequence = 2 or higher)

The terminal units operate to satisfy a heating or cooling load in a zone based on a zone thermostat temperature set point. A direct-expansion (DX) cooling and/or DX heating coil is specified depending on the operating mode required. Both a DX cooling and DX heating coil will typically be installed in the terminal unit, however only one may be used if desired. Outdoor ventilation air is modeled with the use of an optional outside air mixer object. Outside air may be provided to the zone only when the coil is operating or can be supplied continuously even when the coil is not operating. A supply air fan is also required and can be modeled as either draw through or blow through.

Field: Zone Terminal Unit Name

This alpha field defines a unique user-assigned name for an instance of a variable refrigerant flow zone terminal unit. Any reference to this terminal unit by another object will use this name. The zone terminal unit name must be specified in a ZoneTerminalUnitList object to connect this terminal unit to an AirConditioner:VariableRefrigerantFlow object.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the terminal unit operates during a given time period. A schedule value equal to 0 denotes that the terminal unit must be off for that time period. A value greater than 0 denotes that the terminal unit is available to operate during that time period. This schedule may be used to completely disable the terminal unit as required.

Field: Terminal Unit Air Inlet Node Name

This alpha field defines the name of the terminal unit air inlet node. This node name should be the same as a zone exhaust node (ref: ZoneHVAC:EquipmentConnections).

Field: Terminal Unit Air Outlet Node Name

This alpha field defines the name of the terminal unit air outlet node. This node name should be the same as a zone inlet node (ref: ZoneHVAC:EquipmentConnections).

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in cooling mode.

Field: Supply Air Flow Rate When No Cooling is Needed

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit's cooling coil is not operating and the previous mode was cooling.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in heating mode.

Field: Supply Air Flow Rate When No Heating is Needed

This numeric field defines the terminal unit's operating volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit's heating coil is not operating and the previous mode was heating.

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in cooling mode.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is operating in heating mode.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air volumetric air flow rate in cubic meters per second. This volumetric air flow rate is used when the terminal unit is not operating in cooling or heating mode.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field defines the name of the supply air fan operating mode schedule. Schedule values equal to 0 denote cycling fan/cycling coil operation. All other schedule values denote constant fan/cycling coil operation.

Field: Supply Air Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. If this field is left blank, the default is blow through.

The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils. The fan “blows through” the cooling and heating coils. If an outside air mixer is used, the fan inlet connects to the outside air mixer’s mixed air node. If an outside air mixer is not used, the fan inlet connects to the zone exhaust node. For this configuration, the fan outlet always connects to the DX cooling coil inlet node (or if a DX cooling coil is not used, the DX heating coil inlet node).

The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan. The fan “draws air through” the DX coil(s). In this case the fan inlet

always connects to the DX heating coil outlet node (or if a DX heating coil is not used, the DX cooling coil outlet node) and the fan outlet node always connects to the zone inlet node.

Field: Supply Air Fan Object Type

This choice field contains the identifying type of supply air fan specified for the furnace. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Air Fan Object Name

This alpha field defines the name of the terminal unit's supply air fan.

Field: Outside Air Mixer Object Type

This alpha field contains the identifying type of outside air mixer specified for the terminal unit. Outside air mixer type must be **OutsideAir:Mixer**. This field should be left blank when an outside air mixer is not simulated.

Field: Outside Air Mixer Object Name

This alpha field defines the name of the terminal unit's outside air mixer. If this field is left blank, an outside air mixer is not simulated.

Field: DX Cooling Coil Object Type

This choice field contains the identifying type of the terminal unit's DX cooling coil. The only valid DX cooling coil type is **Coil:Cooling:DX:VariableRefrigerantFlow**. This field should be left blank when a DX cooling coil is not simulated.

Field: DX Cooling Coil Name

This alpha field defines the name of the terminal unit's DX cooling coil. If this field is left blank, a DX cooling coil is not simulated.

Field: DX Heating Coil Object Type

This choice field contains the identifying type of the terminal unit's DX heating coil. The only valid DX heating coil type is **Coil:Heating:DX:VariableRefrigerantFlow**. This field should be left blank when a DX heating coil is not simulated.

Field: DX Heating Coil Object Name

This alpha field defines the name of the terminal unit's DX heating coil. This field should be left blank when a DX heating coil is not simulated.

Field: Zone Terminal Unit On Parasitic Electric Energy Use

This numeric field defines the parasitic electrical energy use of the zone terminal unit when either terminal unit coil is operating. When in cooling mode, this electric energy use is reported in a zone terminal unit cooling electric consumption output variable. When in heating mode, this electric energy use is reported in a zone terminal unit heating electric consumption output variable.

Field: Zone Terminal Unit Off Parasitic Electric Energy Use

This numeric field defines the parasitic electrical energy use of the zone terminal unit when the terminal unit coil(s) is not operating. When the previous mode was cooling, this electric energy use is reported in a zone terminal unit cooling electric consumption output variable. When the previous mode was heating, this electric energy use is reported in a zone terminal unit heating electric consumption output variable.

Field: Rated Total Heating Capacity Sizing Ratio

This numeric field defines the ratio of the heating coil to cooling coil size when autosizing is used. The model assumes that when used, this value will be greater than 1. This field supersedes the Rated Total Heating Capacity Sizing Ratio entered in the AirConditioner:VariableRefrigerantFlow object. If this field is left blank, the value entered in the parent object is used for sizing. If neither field is used, the sizing ratio is assumed to be 1.

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this Zone Terminal Unit object's fan. If the Zone Terminal Unit is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this Zone Terminal Unit object should be on or off.

Following is an example input for a ZoneHVAC:TerminalUnit:VariableRefrigerantFlow object.

```

Zone Terminal Unit Total Cooling Rate [W]

This field is the total (sensible and latent) cooling rate output of the terminal unit in Watts. This is determined by terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total energy rate delivered to the zone.

Zone Terminal Unit Total Cooling Energy [J]

This is the total (sensible plus latent) cooling output of the terminal unit in Joules over the time step being reported. This is determined by the terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total cooling energy delivered to the zone.

Zone Terminal Unit Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate output of the terminal unit in Watts. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible cooling energy rate delivered to the zone.

Zone Terminal Unit Sensible Cooling Energy [J]

This is the moist air sensible cooling output of the terminal unit in Joules for the time step being reported. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible cooling energy delivered to the zone.

Zone Terminal Unit Latent Cooling Rate [W]

This is the latent cooling rate output of the terminal unit in Watts. This is determined by the inlet and outlet air humidity ratios and the air mass flow rate through the unit. This value describes the latent cooling energy rate delivered to the zone.

Zone Terminal Unit Latent Cooling Energy [J]

This is the latent cooling output of the terminal unit in Joules for the time step being reported. This is determined by the inlet and outlet air humidity ratios and the air mass flow rate through the unit. This value describes the latent cooling energy delivered to the zone.

Zone Terminal Unit Total Heating Rate [W]

This field is the total enthalpic heating rate output of the terminal unit in Watts. This is determined by the terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total heating energy rate delivered to the zone.

Zone Terminal Unit Total Heating Energy [J]

This is the total enthalpic heating output of the terminal unit in Joules over the time step being reported. This is determined by the terminal unit inlet and outlet air conditions and the air mass flow rate through the unit. This value describes the total heating energy delivered to the zone.

Zone Terminal Unit Sensible Heating Rate [W]

This output is the moist air sensible heating rate output of the terminal unit in Watts. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible heating energy rate delivered to the zone.

Zone Terminal Unit Sensible Heating Energy [J]

This is the moist air sensible heating output of the terminal unit in Joules for the time step being reported. This is determined by enthalpy difference between the inlet and outlet air temperature at a constant humidity ratio, using the minimum of the inlet and outlet air node humidity ratios, and the air mass flow rate through the unit. This value describes the sensible heating energy delivered to the zone.

Zone Terminal Unit Latent Heating Rate [W]

This is the latent heating rate output of the terminal unit in Watts. This is determined by the inlet and outlet air specific humidity ratios and the air mass flow rate through the unit. This value describes the latent heating energy rate delivered to the zone.

Zone Terminal Unit Latent Heating Energy [J]

This is the latent heating output of the terminal unit in Joules for the time step being reported. This is determined by the inlet and outlet air specific humidity ratios and the air mass flow rate through the unit. This value describes the latent heating energy delivered to the zone.

Zone Terminal Unit Cooling Electric Consumption Rate[W]

This output field is the parasitic electricity consumption rate of the zone terminal unit in Watts. The consumption rate includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The terminal unit parasitic on and off electricity is reported in this cooling output variable when the unit operates in cooling mode or the most recent operation was for cooling.

Zone Terminal Unit Cooling Electric Consumption[J]

This output field is the electricity consumption of the zone terminal unit in Joules for the time period being reported. The consumption includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. The terminal unit parasitic on and off electricity consumption is reported in this cooling output variable when the unit operates in cooling mode or the most recent operation was for cooling. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Zone Terminal Unit Heating Electric Consumption Rate[W]

This output field is the parasitic electricity consumption rate of the zone terminal unit in Watts. The consumption rate includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The terminal unit parasitic on and off electricity is reported in this heating output variable when the unit operates in heating mode or the most recent operation was for heating.

Zone Terminal Unit Heating Electric Consumption[J]

This output field is the electricity consumption of the zone terminal unit in Joules for the time period being reported. The consumption includes parasitic electricity used by the zone terminal unit's transformers, controls, or other electricity consuming devices. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. The terminal unit parasitic on and off electricity consumption is reported in this heating output variable when the unit operates in heating mode or the most recent operation was for heating. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter).

Zone Terminal Unit Fan Availability Status []

This is the availability status of the Zone Terminal Unit fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the Zone Terminal Unit object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:^{*} Outputs). For multiple availability managers in an Availability Manager Assignment List along with Hybrid Ventilation Manager, rules to determine fan availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the "detailed" reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

Group – Unitary Equipment

Furnace and Unitary Systems

The components

```
AirLoopHVAC:Unitary:Furnace:HeatOnly  
AirLoopHVAC:Unitary:Furnace:HeatCool  
AirLoopHVAC:UnitaryHeatOnly  
AirLoopHVAC:UnitaryHeatCool  
AirLoopHVAC:UnitaryHeatPump:AirToAir  
AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed
```

are compound components usually placed in the primary air loop as the sole component. On the zone equipment side they are usually connected to one or more zones through uncontrolled terminal units (i.e., AirTerminal:SingleDuct:Uncontrolled objects). The maximum or design air flow rate through the furnace or unitary system should usually be set equal to the sum of the maximum air flow rates through the terminal unit objects. However, the simulation program can usually account for unequal air flows if the user wishes to model this scenario.

AirLoopHVAC:Unitary:Furnace:HeatCool

The heat/cool furnace is a "virtual" component that consists of a fan component (OnOff or ConstantVolume), a DX cooling coil component, and a Gas or Electric heating coil component. The blow through furnace configuration is shown in Figure 103 below. When a draw through furnace configuration is desired, the fan is placed directly after the heating coil. If the dehumidification control type is specified as CoolReheat, a reheat coil component is also required. If the reheat coil is present and the dehumidification control type input is not specified as CoolReheat, the reheat coil will not be active,

Figure 103. Schematic of EnergyPlus Heat/Cool Furnace

Note: the coil order shown here has been revised from previous versions (prior to V4.0) of Energyplus to configure the cooling coil upstream of the heating coil. This configuration provides uniformity with all unitary equipment. However, for unitary HeatCool systems that do not use a reheat coil, the heating coil can also be placed upstream of the cooling coil. This optional coil placement is retained to allow compatibility with previous versions of Energyplus. For input files developed using previous versions of Energyplus, it is recommended that the coil order be revised according to the figure above.

Links to the fan, heating coil, DX cooling coil and optional reheat coil specifications are provided in the furnace input data syntax. In addition, the control zone name and the furnace design operating conditions are specified by the furnace inputs.

Field: Name

This alpha field contains the identifying name for the unit.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the furnace to operate.

Field: Furnace Air Inlet Node Name

This alpha field contains the furnace inlet node name.

Field: Furnace Air Outlet Node Name

This alpha field contains the furnace outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan).

Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design operating furnace air outlet temperature in degrees C when the furnace is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the furnace in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the furnace operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the furnace operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the furnace is located.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the furnace. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the furnace fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the furnace. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. Only allowable coil types are:

Coil:Heating:Electric

Coil:Heating:Gas
Coil:Heating:Water
Coil:Heating:Steam

Field: Heating Coil Name

This alpha field contains the identifying name given to the furnace heating coil.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the furnace. Only allowable coil types are:

Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted

Field: Cooling Coil Name

This alpha field contains the identifying name given to the furnace cooling coil.

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

Multimode - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted.

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. If cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is used. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. If the dehumidification control type is specified as **CoolReheat**, then two additional inputs (reheat coil type and name) are also required as shown below. Although the reheat coil is required only when **CoolReheat** is selected, the optional reheat coil may be present for any of the allowed Dehumidification Control Types. If the reheat coil is present and the dehumidification control type is not specified as **CoolReheat**, the reheat coil will not be active,

Field: Reheat Coil Object Type

This alpha field contains the identifying type of reheat coil specified in the furnace. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. Reheat coil type must be one of:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Desuperheater
Coil:Heating:Water
Coil:Heating:Steam

Field: Reheat Coil Name

This alpha field contains the identifying name given to the furnace reheat coil.

As shown in the example below, correct specification of the heat/cool furnace requires specification of the following objects in addition to the furnace object:

- 1) fan (Fan:OnOff or Fan:ConstantVolume)
- 2) cooling coil (Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted) or
- 3) heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 4) reheat coil (optional, Coil:Heating:Gas, Coil:Heating:Electric, or
Coil:Heating:Desuperheater)
- 5) terminal unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the furnace

Note: the furnace's fan, cooling coil, heating coil and optional reheat coil must be connected in the air loop according to the configuration shown above (Figure 103) when CoolReheat is selected as the dehumidification control type. In addition, the volumetric air flow rate specified in the terminal air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the furnace object.

Example of Heat/Cool Furnace Specification

AirLoopHVAC:Unitary:Furnace:HeatCool Outputs

HVAC,Average,Furnace Fan Part-Load Ratio
 HVAC,Average,Furnace Compressor Part-Load Ratio

Furnace Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the furnace to the furnace's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state furnace heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the furnace fan may be different from the fan part-load ratio reported here due the part-load performance of the furnace's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

Furnace Compressor Part-Load Ratio

This output variable is the ratio of the sensible cooling load to the steady-state cooling capacity of the furnace's DX cooling coil. The runtime fraction for the DX cooling coil compressor may be different from the compressor part-load ratio reported here due the part-load performance of the cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

AirLoopHVAC:UnitaryHeatCool

The AirLoopHVAC:UnitaryHeatCool object is the identical model to the AirLoopHVAC:Unitary:Furnace:HeatCool object. The heat/cool unitary system is a "virtual" component that consists of a fan component (OnOff or ConstantVolume), a DX cooling coil component and a Gas or Electric heating coil component as shown in Figure 104. When a draw through configuration is desired, the fan is placed directly after the heating coil. If dehumidification control is selected, a reheat coil component is also required. If the reheat

coil is present and the dehumidification control type input is not specified as CoolReheat, the reheat coil will not be active,

Figure 104. Schematic of Blow Through Heat/Cool Unitary System

Note: the coil order shown here has been revised from previous versions (prior to V4.0) of EnergyPlus to configure the cooling coil upstream of the heating coil. This configuration provides uniformity with all unitary equipment. However, for unitary HeatCool systems that do not use a reheat coil, the heating coil can also be placed upstream of the cooling coil. This optional coil placement is retained to allow compatibility with previous versions of EnergyPlus. For input files developed using previous versions of EnergyPlus, it is recommended that the coil order be revised according to the figure above.

Links to the fan, DX cooling coil, heating coil and optional reheat coil specifications are provided in the unitary system input data syntax. In addition, the control zone name and the system design operating conditions are specified by the unitary system inputs.

Field: Name

This alpha field contains the identifying name for the unitary system.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the unitary system to operate.

Field: Unitary System Air Inlet Node Name

This alpha field contains the unitary system inlet node name.

Field: Unitary System Air Outlet Node Name

This alpha field contains the unitary system outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change

of season. Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design operating air outlet temperature in degrees C when the unitary system is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the unitary system in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the unitary system operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the unitary system operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the unitary system is located.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the unitary system. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the unitary system fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the DX coils and supplemental heating coil. The fan “blows through” the cooling and heating coils. The second choice stands for “draw through fan”. This means that the unit consists of the DX coil(s) followed by a fan, with the supplemental heater located at the outlet of the fan. The fan “draws air through” the DX coil(s). If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector

objects to support the heating coils, and are placed on the demand side of the plantloop. Only allowable coil types are:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Water
Coil:Heating:Steam

Field: Heating Coil Name

This alpha field contains the identifying name given to the unitary system heating coil.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the unitary system. Only allowable coil types are:

Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted

Field: Cooling Coil Name

This alpha field contains the identifying name given to the unitary system cooling coil.

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

Multimode - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted.

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. If cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is used. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. If the dehumidification control type is specified as **CoolReheat**, then two additional inputs (reheat coil type and name) are also required as shown below. Although the reheat coil is required only when **CoolReheat** is selected, the optional reheat coil may be present for any of the allowed Dehumidification Control Types. If the reheat coil is present and the dehumidification control type is not specified as **CoolReheat**, the reheat coil will not be active,

Field: Reheat Coil Object Type

This alpha field contains the identifying type of reheat coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. Reheat coil type must be one of:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Desuperheater
Coil:Heating:Water
Coil:Heating:Steam

Field: Reheat Coil Name

This alpha field contains the identifying name given to the unitary system reheat coil.

As shown in the example below, correct specification of the heat/cool unitary system requires specification of the following objects in addition to the unitary system object:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) Cooling coil (Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted) or
- 3) Heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 4) Reheat coil (optional, Coil:Heating:Gas, Coil:Heating:Electric, Coil:Heating:Desuperheater) or
- 5) Direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the unitary system

Note: the unitary system's fan, cooling coil, heating coil and optional reheat coil must be connected in the air loop according to the configuration shown above (Figure 104). In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the unitary system object.

Example of Heat/Cool Unitary System Specification

AirLoopHVAC:UnitaryHeatCool Outputs

HVAC,Average, Unitary System Fan Part-Load Ratio
HVAC,Average, Unitary System Compressor Part-Load Ratio

Unitary System Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the unitary system to the system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state unitary system heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the unitary system fan may be different from the fan part-load ratio reported here due the part-load performance of the system's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

Unitary System Compressor Part-Load Ratio

This output variable is the ratio of the sensible cooling load to the steady-state cooling capacity of the unitary system's DX cooling coil. The runtime fraction for the DX cooling coil compressor may be different from the compressor part-load ratio reported here due the part-load performance of the cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

AirLoopHVAC:UnitaryHeatPump:AirToAir

The unitary air-to-air heat pump is a “virtual” component that consists of a fan component (OnOff or ConstantVolume), a DX cooling coil component, a DX heating coil component, and a Gas or Electric supplementary heating coil component as shown in the Figure below.

Figure 105. Schematic of EnergyPlus Unitary Air-to-Air Heat Pump (Blow Through Configuration)

Links to the fan, DX cooling coil, DX heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. In addition the control zone name and the system design operating conditions are specified by the heat pump inputs.

Field: Name

This alpha field contains the identifying name for the unitary system heat pump.

Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

Field: Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating. Values must be greater than 0 or this field is autosizable.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling or heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump operating mode is specified as continuous fan operation. Values must be greater than or equal to zero, or this field is autosizable. If the heat pump operating mode is specified as continuous fan operation and this value is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the heat pump is located.

Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the heat pump. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil type must be:

Coil:Heating:DX:SingleSpeed

Field: Heating Coil Name

This alpha field contains the identifying name given to the heat pump DX heating coil, and should match the name specified in the corresponding DX heating coil object.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. There are two valid choices for this field:

Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted

Field: Cooling Coil Name

This alpha field contains the identifying name given to the heat pump cooling coil, and should match the name specified in the corresponding DX cooling coil object.

Field: Supplemental Heating Coil Object Type

This alpha field contains the identifying type of supplemental heating coil specified in the heat pump. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. Heating coil type must be:

```
Coil:Heating:Electric  
Coil:Heating:Gas  
Coil:Heating:Water  
Coil:Heating:Steam
```

Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the heat pump supplemental heating coil, and should match the name specified in the corresponding heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the DX cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply air fan is between the DX cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the unitary system supply air fan and the heating or cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating or cooling coil cycles to meet the load.

As shown in the example below, correct specification of the air-to-air heat pump requires specification of the following objects in addition to the heat pump object:

- 1) Fan (Fan:OnOff or Fan:ConstantVolume)
- 2) Heating coil (Coil:Heating:DX:SingleSpeed)
- 3) Cooling coil (Coil:Cooling:DX:SingleSpeed)
CoilSystem:Cooling:DX:HeatExchangerAssisted) or
- 4) Supplemental heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 5) Direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the unitary system

Field: Dehumidification Control Type

This alpha input field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

Multimode - activate enhanced dehumidification mode as needed and meet sensible cooling load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted.

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. The excess cooling beyond the cooling set point temperature is offset by the supplemental heating coil. If cooling coil type = CoilSystem:Cooling:DX:HeatExchangerAssisted, then the heat exchanger is assumed to always transfer energy between the cooling coil's inlet and outlet airstreams when the cooling coil is operating.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint is required. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. Supplemental heating coil (supplemental heating coil type and name) is a required input in AirToAir HeatPumps. The supplemental heating coil capacity must be adequate enough to meet the heating coil load and offset the excess cooling load due to extra dehumidification required to meet the high relative humidity setpoint.

Note: the air-to-air heat pump's fan, cooling coil, heating coil and supplementary heating coil must be connected in the air loop according to the configuration shown above (Figure 105) for the blow-through fan configuration. The only other valid configuration is with a draw-through fan placement, where the fan is located between the DX heating coil and the supplementary heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the heat pump object.

```

AirLoopHVAC:UnitaryHeatPump:AirToAir Outputs

HVAC, Average, Unitary Heat Pump Fan Part-Load Ratio
HVAC, Average, Unitary Heat Pump Compressor Part-Load Ratio
HVAC, Average, Heat Pump Dehumidification Induced Heating Demand Rate [W]

Unitary Heat Pump Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the heat pump to the heat pump's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state heat pump heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the heat pump fan may be different from the fan part-load ratio reported here due the part-load performance of the heat pump's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

Unitary Heat Pump Compressor Part-Load Ratio

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the heat pump's DX heating or cooling coil. The runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due the part-load performance of the heating/cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

Heat Pump Dehumidification Induced Heating Demand Rate

This output variable is the additional heating demand rate of the supplemental heating coil of an Air-to-Air heat pumps in Watts. This additional heating demand is induced when zone air overshoots the heating setpoint due to extra dehumidification requirement to meet the high humidity setpoint. This value is always positive. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed

The multispeed air-to-air heat pump is a “virtual” component that consists of a fan component (On/Off or ConstVolume), a DX multispeed cooling coil component, a DX multispeed heating coil component, and a Gas or Electric supplemental heating coil component. This system also includes the option to use available waste energy to heat water. A schematic diagram of the air-to-air multispeed heat pump is shown below. The component connection sequence for the blow through option (shown below) from inlet to outlet is fan, cooling coil, heating coil, and supplemental heater. The connection sequence for the draw through option is cooling coil, heating coil, fan, and supplemental heater.

Figure 106. Schematic of EnergyPlus Unitary Air-to-Air Multi Speed Heat Pump

The main difference between this heat pump object and other EnergyPlus heat pump objects is that this object allows from two to four discrete compressor speeds for heating and cooling operation (instead of a single speed for each mode). The lowest speed is called Speed 1, and the highest speed is called Speed n (2, 3 or 4 as specified in the input syntax). This object allows a different number of speeds for cooling and heating, and each speed has an associated airflow rate. The airflow rates for the various heating speeds can be different from the airflow rates for the cooling speeds. In addition, the airflow rate when no cooling or heating is needed can also be defined. The number of cooling and heating speeds defined by the user in this heat pump object must equal the number of speeds defined in the associated coils (child objects). For example, the number of speeds for cooling defined in this heat pump object must be equal to the number of speeds defined in the associated cooling coil object.

Links to the fan, DX multispeed cooling coil, DX multispeed heating coil, and supplementary heating coil specifications are provided in the heat pump’s input data syntax. In addition, the control zone name and airflow rates at the corresponding compressor speeds are specified by the heat pump syntax.

Field: Name

This alpha field contains the identifying name for the multispeed heat pump.

Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the multispeed heat pump is located.

Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the heat pump. Fan type must be Fan:OnOff or Fan:ConstantVolume. Fan:ConstantVolume can only be used when the supply air fan operating mode is continuous (see field 'Supply air fan operating mode schedule name').

Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

Field: Supply Air Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for "blow through fan". This means that the unit consists of a fan followed by a DX multispeed cooling coil, DX multispeed heating coil, and a supplemental heating coil. The fan "blows through" the cooling and heating coils. The second choice stands for "draw through fan". This means that the unit consists of the DX cooling and heating coils followed by a fan, with the supplemental heater located at the outlet of the fan. The fan "draws" air through the DX coils.

Note: the multispeed heat pump's supply air fan, cooling coil, heating coil and supplemental heating coil must be connected according to the configuration shown above (Figure 106) for the 'blow through' fan configuration. For the 'draw through' fan configuration the fan must be located between the DX heating coil and the supplemental heater, whose outlet node is the system outlet node. In addition, the DX cooling coil and DX heating coil operation mode must be specified consistently with the heat pump's supply air fan operating mode (e.g., with the heat pump's supply air fan set to cycle on and off with the cooling/heating load, the DX cooling and heating coil operation mode must be *CyclingFanAndCompressor*). If the operation modes in the parent (heat pump) and child (coil) objects are specified differently, the operation mode in the parent object prevails.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information to control the supply air fan. Schedule values of zero mean that the supply air fan will cycle off if

there is no cooling or heating load in the control zone. Non-zero schedule values mean that the supply air fan will operate continuously even if there is no cooling or heating load in the control zone. If this field is left blank, the supply air fan will operate continuously for the entire simulation period.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil type must be Coil:Heating:DX:MultiSpeed.

Field: Heating Coil Name

This alpha field contains the identifying name given to the DX heating coil, and should match the name specified in the corresponding DX heating coil object.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the outdoor air dry-bulb temperature below which the DX heating coil turns off. The temperature for this input field must be greater than or equal to -20 C. If this input field is left blank, the default value is -8 C. This temperature should match the minimum compressor operating temperature specified for the multispeed heat pump's DX heating coil.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. Cooling coil type must be Coil:Cooling:DX:MultiSpeed.

Field: Cooling Coil Name

This alpha field contains the identifying name given to the heat pump cooling coil, and should match the name specified in the corresponding DX cooling coil object.

Field: Supplemental Heating Coil Object Type

This alpha field contains the identifying type of supplemental heating coil specified in the heat pump. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. Heating coil type must be:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Water
Coil:Heating:Steam

Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the heat pump supplemental heating coil, and should match the name specified in the corresponding heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature (in degrees C) exiting the heat pump supplemental heating coil. If the calculated supply air temperature exiting the supplemental heater exceeds this value, then it is reset to this maximum temperature. This field is autosizable.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Auxiliary On-Cycle Electric Power

This field defines auxiliary electrical power (W) consumed during the on-cycle period (i.e., when the cooling or heating coil is operating). The model assumes that this auxiliary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

Field: Auxiliary Off-Cycle Electric Power

This field defines auxiliary electrical power (W) consumed during the off-cycle period (i.e., when the cooling and heating coil are not operating). The model assumes that this auxiliary power does not contribute to heating the supply air. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

Field: Design Heat Recovery Water Flow Rate

This optional input field defines the design water flow rate used if the heat recovery option is being simulated. If this value is greater than 0.0 then a heat recovery loop must be specified and attached to the multispeed heat pump using the next 2 node fields. To determine how the heat recovery algorithm works, refer to the EnergyPlus Engineering Reference in the AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed with Heat Recovery section. The units for this input value are cubic meters per second.

Field: Maximum Temperature for Heat Recovery

This field sets the maximum temperature (in degrees C) that this heat pump can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperature leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

Field: Heat Recovery Water Inlet Node Name

This alpha field contains the identifying name for the heat recovery side inlet node.

Field: Heat Recovery Water Outlet Node Name

This alpha field contains the identifying name for the heat recovery side outlet node.

Field: Supply Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when neither cooling nor heating is required (i.e., DX coils and supplemental heater are off but the supply air fan operates). This field is only used when the heat pump supply air fan is scheduled to operate continuously regardless of DX coil operation (ref. field "Supply air fan operating mode schedule"). Values must be greater than or equal to zero, or this field is autosizable. If the heat pump supply air fan is scheduled to operate continuously and the input value for this field is set to zero or this field is left blank, then the model assumes that the supply air flow rate when no cooling/heating is needed is equal to the supply air flow rate when the compressor was last operating (for cooling operation or heating operation).

Field: Number of Speeds for Heating

This field defines the number of heating speeds for the heat pump, and must match the number of heating speeds defined in the associated heating coil. The value for this input field defines the number of airflow rates that must be defined for heating in the field below. The minimum value for this field is two and the maximum value is four.

Field: Number of Speeds for Cooling

This field defines the number of cooling speeds for the heat pump, and must match the number of cooling speeds defined in the associated DX cooling coil. The value for this input field defines the number of airflow rates that must be defined for cooling in the field below. The minimum value for this field is two and the maximum value is four.

Field: Speed 1 Supply Air Flow Rate During Heating Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 1 (lowest speed). Values must be greater than 0 or this field is autosizable.

Field: Speed 2 Supply Air Flow Rate During Heating Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 2. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 1.

Field: Speed 3 Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 3. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 2. If the 'Number of Speeds for Heating' is less than 3, then this field can be left blank.

Field: Speed 4 Supply Air Flow Rate During Heating Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX heating coil and/or supplemental heater are operating at Speed 4 (high speed). Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for heating Speed 3. If the 'Number of Speeds for Heating' is less than 4, then this field can be left blank.

Note: When autosizable is selected for any of the supply air volumetric flow rate fields, all supply air flow fields at the different speeds must be specified as autosizable. Otherwise, a fatal error will be issued and the simulation will terminate.

Field: Speed 1 Supply Air Flow Rate During Cooling Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 1 (lowest speed). Values must be greater than 0 or this field is autosizable.

Field: Speed 2 Supply Air Flow Rate During Cooling Operation

This required numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 2. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 1.

Field: Speed 3 Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 3. Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 2. If the 'Number of Speeds for Cooling' is less than 3, then this field can be left blank.

Field: Speed 4 Supply Air Flow Rate During Cooling Operation

This numeric field defines the supply air flow rate leaving the heat pump in cubic meters per second when the DX cooling coil is operating at Speed 4 (highest speed). Values must be greater than 0 or this field is autosizable. If not autosized, the entered value must be greater or equal to the flow rate specified for cooling Speed 3. If the 'Number of Speeds for Cooling' is less than 4, then this field can be left blank.

Following is an example input for the object and its associated components.

Unitary MSHP Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the multispeed heat pump to the heat pump's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate) at Speed 1. For continuous fan operation mode, this variable is always 1.0 when the heat pump is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating (or cooling) load to the steady-state heat pump heating (or cooling) capacity. For the cycling fan mode, the runtime fraction for the heat pump fan may be different from the fan part-load ratio reported here due the part-load performance of the heat pump's heating (or cooling) coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff). When the speed number is greater than 1, the value is 1.0.

Unitary MSHP Compressor Part-Load Ratio

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the multispeed heat pump's DX heating or cooling coil at Speed 1. The runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due the part-load performance of the heating/cooling coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate. When the speed number is greater than 1, the value is 1.0.

Unitary MSHP DX Coil Cycling Ratio

This output variable is the ratio of the sensible load (heating or cooling) to the steady-state capacity of the multispeed heat pump's DX heating or cooling coil (Speed 1) for the entire system timestep. The value is between 0.0 and 1.0 when the heat pump is cycling on and off its lowest speed (Speed 1) and 1.0 when the multispeed heat pump operates at speeds above 1.

Unitary MSHP DX Coil Speed Ratio

This output variable is the ratio of time in a system timestep that the compressor is at rated speed between two consecutive speed numbers ([Compressor Speed - Compressor speed at Speed i-1] / [Compressor speed at Speed i - Compressor speed at Speed i-1]). The compressor speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep. The value is 0.0 during Speed 1 operation.

The physical meaning of the speed ratio is dependent on the compressor configuration defined in the field of child coil object: Apply Part Load Fraction to Speeds greater than 1. The allowed choice is either Yes or No. When No is entered, one compressor is assumed for all speeds. The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the lower speed runs in the rest of the system timestep. When Yes is entered, multiple compressors are assumed, and each compressor has associated speed.

The speed ratio represents how long the higher speed runs as a fraction of the system timestep, and the low speed runs in a whole system timestep.

Unitary MSHP DX Coil Speed Number

This output variable reports the maximum speed needed when the heat pump operates to meet the sensible load (heating or cooling) in a system timestep. When the value is 1, the heat pump operates at Speed 1 (lowest speed). For this case the cycling ratio is between 0.0 and 1.0, while the speed ratio is 0.0. When the speed number output variable is above one, such as 1, the heat pump operation is determined by the speed ratio through linear interpolation. For example, when the speed ratio is 0.4 and the speed number is 3, the heat pump operates at Speed 3 for 40% of a system timestep and at Speed 2 for 60% of a system timestep for a single compressor. For multiple compressors, the heat pump operates at Speed 3 in the 40% of a system timestep and at Speed 2 in the whole system timestep.

Unitary MSHP Total Heating Energy Rate [W]

This output field is the total (enthalpy) heat addition rate of the multispeed heat pump to the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Unitary MSHP Total Cooling Energy Rate [W]

This output field is the total (enthalpy) heat extraction rate of the multispeed heat pump from the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Unitary MSHP Sensible Heating Energy Rate [W]

This output field reports the sensible heat addition rate of the multispeed heat pump to the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Unitary MSHP Sensible Cooling Energy Rate [W]

This output field reports the moist air sensible heat extraction rate of the multispeed heat pump from the zones it is serving in Watts. This value is calculated using the enthalpy difference of the heat pump outlet air and inlet air streams at a constant humidity ratio, and the air mass flow rate through the heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Unitary MSHP Latent Heating Energy Rate [W]

This output field is the latent heat addition (humidification) rate of the multispeed heat pump in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the multispeed heat pump. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Unitary MSHP Latent Cooling Energy Rate [W]

This output field is the latent heat extraction (dehumidification) rate of the multispeed heat pump in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the multispeed heat pump. This value is calculated for

each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Unitary MSHP Electric Power [W]

This output field is the electricity consumption rate of the multispeed heat pump in Watts. The consumption includes electricity used by the DX coils (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported. Any non-electric energy use is not reported by the heat pump object but is reported in the associated coil objects as appropriate.

Unitary MSHP Electric Consumption [J]

This output field is the electricity consumption of the multispeed heat pump in Joules for the timestep being reported. The consumption includes electricity used by the DX compressor (including crankcase heater if the fuel type is electricity), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), auxiliary power during on and off period, and the supplemental heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported. Any non-electric energy use is not reported by the heat pump object but is reported in the associated coil objects as appropriate.

Unitary MSHP Auxiliary Electric Power [W]

This output field is the average auxiliary electricity consumption rate (including both on-cycle and off-cycle) in Watts for the timestep being reported.

Unitary MSHP Auxiliary Electric Cooling Consumption [J]

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the heat pump is providing cooling (DX cooling coil is operating). This output is also added to a report meter with Resource Type = Electricity, End Use Key =Cooling, Group Key = System (ref. Report Meter).

Unitary MSHP Auxiliary Electric Heating Consumption [J]

This is the auxiliary electricity consumption in Joules for the timestep being reported. This is the auxiliary electricity consumption during periods when the heat pump is providing heating (DX heating coil is operating). This output is also added to a report meter with Resource Type = Electricity, End Use Key =Heating, Group Key = System (ref. Report Meter).

Unitary MSHP Waste Heat Recovery Inlet Temp [C]

Unitary MSHP Waste Heat Recovery Outlet Temp [C]

Unitary MSHP Waste Heat Recovery Mass Flow Rate [kg/s]

These outputs are the heat recovery inlet and outlet temperatures and water mass flow rate for multispeed heat pumps with heat recovery.

Unitary MSHP Waste Heat Recovery Rate [W]

Unitary MSHP Waste Heat Recovery Energy [J]

For multispeed heat pumps with heat recovery, these outputs are the recoverable energy rate (in Watts) and energy (in Joules).

AirLoopHVAC:Unitary:Furnace:HeatOnly

The EnergyPlus furnace is a “virtual” component that consists of a fan component (OnOff or ConstantVolume) and a Gas or Electric heating coil component. The blow through furnace configuration is shown in the Figure below.

Figure 107. Schematic of Blow Through Furnace Model

Links to the fan and heating coil specifications are provided in the furnace input data syntax. In addition the control zone name and the furnace design operating conditions are specified by the furnace inputs.

Field: Name

This alpha field contains the identifying name for the furnace.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the furnace to operate.

Field: Furnace Inlet Node Name

This alpha field contains the furnace inlet node name.

Field: Furnace Outlet Node Name

This alpha field contains the furnace outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating coil cycle on and off together to meet the heating load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design operating furnace air outlet temperature in degrees C when the furnace is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate

This numeric field contains the design volumetric flow rate of the furnace in cubic meters per second. This volumetric flow rate should match the flow rate specified for the furnace fan.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the furnace is located.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the furnace. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the furnace fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for “blow through fan”. This means that the unit consists of a fan followed by the heating coil. The fan “blows through” the heating coil. The second choice stands for “draw through fan”. This means that the unit consists of the heating coil followed by a fan. The fan “draws air through” the heating coil. If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the furnace. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. Heating coil type must be:

```
Coil:Heating:Electric  
Coil:Heating:Gas  
Coil:Heating:Water  
Coil:Heating:Steam
```

Field: Heating Coil Name

This alpha field contains the identifying name given to the furnace heating coil.

As shown in the example below, correct specification of the furnace requires specification of the following objects in addition to the furnace object:

- 1) fan (Fan:OnOff or Fan:ConstantVolume)
- 2) heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 3) direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the furnace

Note: the furnace's fan and heating coil must be connected in the air loop according to the configuration shown above (Figure 107) when a blow through fan configuration is specified. If a draw through fan is used, the fan is located down stream of the heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the furnace object.

Example of Heat-Only Furnace Specification

AirLoopHVAC:Unitary:Furnace:HeatOnly Outputs

HVAC,Average,Furnace Fan Part-Load Ratio
--

Furnace Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the furnace to the furnace's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the furnace is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating load to the furnace heating capacity. For the cycling fan mode, the runtime fraction for the furnace fan may be different from the fan part-load ratio reported here due the part-load performance of the furnace's heating coil (delay at start-up to reach steady-state heating output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

AirLoopHVAC:UnitaryHeatOnly

The AirLoopHVAC:UnitaryHeatOnly is identical to the AirLoopHVAC:Unitary:Furnace:HeatOnly model. The heat-only unitary system is a "virtual" component that consists of a fan component (OnOff or ConstantVolume) and a Gas or Electric heating coil component. The blow through unitary system configuration is shown in the Figure below.

Figure 108. Schematic of Blow Through Heat-Only Unitary System

Links to the fan and heating coil specifications are provided in the unitary system input data syntax. In addition, the control zone name and the unitary system design operating conditions are specified by the unitary system syntax.

Field: Name

This alpha field contains the identifying name for the unitary system.

Field: Availability Schedule Name

This alpha field contains the schedule name which contains information on the availability of the unitary system to operate.

Field: Unitary System Air Inlet Node Name

This alpha field contains the unitary system inlet node name.

Field: Unitary System Air Outlet Node Name

This alpha field contains the unitary system outlet node name.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the furnace supply air fan and the heating coil cycle on and off together to meet the heating load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply fan runs continuously while the heating coil cycles to meet the load.

Field: Maximum Supply Air Temperature

This numeric field contains the design air outlet temperature in degrees C when the unitary system is heating. If this input field is left blank, the default value is 80 C.

Field: Supply Air Flow Rate

This numeric field contains the design volumetric flow rate of the unitary system in cubic meters per second. This volumetric flow rate should match the flow rate specified for the unitary system fan.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the unitary system is located.

Field: Supply Fan Object Type

This alpha field contains the identifying type of supply air fan specified for the unitary system. Fan type must be **Fan:OnOff** or **Fan:ConstantVolume**. Fan:ConstantVolume is used when the Supply Air Fan Operating Mode Schedule values are never 0 and the fan operates continuously. Fan:OnOff is used when the fan cycles on and off with the cooling or heating coil (i.e. Supply Air Fan Operating Mode Schedule values are at times 0).

Field: Supply Fan Name

This alpha field contains the identifying name given to the unitary system fan.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice stands for "blow through fan". This means that the unit consists of a fan followed by the heating coil. The fan "blows through" the heating coil. The second choice stands for "draw through fan". This means that the unit consists of the heating coil followed by a fan. The fan "draws air through" the heating coil. If this field is left blank, the default is blow through.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. Heating coil type must be

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Water
Coil:Heating:Steam

Field: Heating Coil Name

This alpha field contains the identifying name given to the unitary system heating coil.

As shown in the example below, correct specification of the heat-only unitary system requires specification of the following objects in addition to the unitary system object:

- 1) fan (Fan:OnOff or Fan:ConstantVolume)
- 2) heating coil (Coil:Heating:Gas or Coil:Heating:Electric)
- 3) direct air unit (AirTerminal:SingleDuct:Uncontrolled) for each zone served by the furnace

Note: the unitary system's fan and heating coil must be connected in the air loop according to the configuration shown above (Figure 108) when a blow through fan configuration is specified. If a draw through fan is used, the fan is located down stream of the heating coil. In addition, the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the unitary system object.

Example of Heat-Only Unitary System Specification

AirLoopHVAC:UnitaryHeatOnly Outputs

HVAC,Average,Unitary System Fan Part-Load Ratio

Unitary System Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the unitary system to the unitary system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule). For cycling fan/cycling coil operation mode, the actual air mass flow rate is calculated based on the ratio of the sensible heating load to the unitary system heating capacity. For the cycling fan mode, the runtime fraction for the unitary system fan may be different from the fan part-load ratio reported here due the part-load performance of the unitary system's heating coil (delay at start-up to reach steady-state heating output). In general, runtime fractions are reported by individual components where appropriate (e.g., Fan:OnOff).

AirLoopHVAC:UnitaryHeatPump:WaterToAir

The unitary water-to-air heat pump is similar to the unitary air-to-air heat pump except water is used on the source side. Links to the fan, WaterToAirHeatPump cooling coil, WaterToAirHeatPump heating coil, and supplementary heating coil specifications are provided in the heat pump's input data syntax. The heat pump switches between cooling and heating depending on the zone's demand. The load side (air) of the unitary water-to-air heat pump consists of an On/Off fan component, a WaterToAirHeatPump cooling coil component, a WaterToAirHeatPump heating coil component, and a Gas, Electric, Steam, or Hot Water supplemental heating coil component. The source side (water) of the heat pump is connected to a condenser loop with a heat exchanger (ground heat exchanger or other type) or a plant loop with a heating source such as a boiler and a cooling source such as a chiller or cooling tower. The diagram below shows the setup and connection of the heat pump for the source side and load side for a ground heat exchanger configuration. Note that on the load side, the WaterToAirHeatPump cooling coil must always be placed before the WaterToAirHeatPump heating coil.

There are two type of WaterToAirHeatPump coil models available:

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
Coil:Heating:WaterToAirHeatPump:ParameterEstimation
Coil:Cooling:WaterToAirHeatPump:EquationFit
Coil:Heating:WaterToAirHeatPump:EquationFit

Figure 109. Water to Air Heat Pump Schematic for a BlowThrough Configuration with Ground Heat Exchanger

In addition, the control zone name and the system design operating conditions are specified by the heat pump inputs.

Field: Name

This alpha field contains the identifying name for the unitary system heat pump.

Field: Availability Schedule Name

This alpha field contains the schedule name (ref. Schedule) that contains information on the availability of the heat pump to operate. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

This alpha field contains the name of the HVAC system node from which the heat pump draws its inlet air.

Field: Air Outlet Node Name

This alpha field contains the name of the HVAC system node to which the heat pump sends its outlet air.

Field: Supply Air Flow Rate

This numeric field contains the design volumetric flow rate through the heat pump in cubic meters per second. This volume flow rate is only used when the cooling and heating coil object type is Coil:*:WaterToAirHeatPump:ParameterEstimation. Although a value greater than 0 is required (input cannot be blank or 0), this input is not used for the EquationFit model. Instead, the supply air flow rate is determined by the input in the corresponding Coil:*:WaterToAirHeatPump:EquationFit objects.

Field: Controlling Zone or Thermostat Location

This alpha field contains the identifying zone name where the thermostat controlling the heat pump is located.

Field: Supply Air Fan Object Type

This alpha field contains the identifying type of supply air fan specified in the heat pump. Fan type must be Fan:OnOff.

Field: Supply Air Fan Name

This alpha field contains the identifying name given to the heat pump supply air fan, and should match the name specified in the corresponding fan object.

Field: Heating Coil Object Type

This alpha field contains the identifying type of heating coil specified in the heat pump. Heating coil types are:

Coil:Heating:WaterToAirHeatPump:ParameterEstimation
Coil:Heating:WaterToAirHeatPump:EquationFit

Field: Heating Coil Name

This alpha field contains the identifying name given to the WaterToAirHeatPump heating coil, and should match the name specified in the corresponding WaterToAirHeatPump heating coil object.

Field: Heating Convergence

This numeric value allows the user to determine how close the air side has to be controlled. Lower the value of convergence better the control of air side conditions and less the zone temperature fluctuations. However in a poorly designed system, a lower convergence might result in warning errors which are caused due to the iteration limit for run time fraction calculation is limited to 20.

Field: Cooling Coil Object Type

This alpha field contains the identifying type of cooling coil specified in the heat pump. Cooling coil types are:

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
Coil:Cooling:WaterToAirHeatPump:EquationFit

Field: Cooling Coil Name

This alpha field contains the identifying name given to the WaterToAirHeatPump cooling coil, and should match the name specified in the corresponding WaterToAirHeatPump cooling coil object.

Field: Cooling Convergence

This numeric value allows the user to determine how close the air side has to be controlled. Lower the value of convergence better the control of air side conditions and less the zone temperature fluctuations. However in a poorly designed system, a lower convergence might

result in warning errors which are caused due to the iteration limit for run time fraction calculation is limited to 20.

Field: Maximum Cycling Rate

This numeric field contains the maximum on-off cycling rate for the compressor, which occurs at 50% run time fraction. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	2.5
Good	2.5
Poor	3.0

Field: Heat Pump Time Constant

This numeric field contains the time constant for the cooling coil's capacity to reach steady state after startup. Suggested values are shown below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	60
Good	60
Poor	60

Field: Fraction of On-Cycle Power Use

This numeric field contains the fraction of on-cycle power use to adjust the part load fraction based on the off-cycle power consumption due to crankcase heaters, controls, fans, and etc. Suggested value values are below (Henderson et al. 1999):

Heat Pump Condition	Recommended Values
Typical	0.01
Good	0.01
Poor	0.03

Field: Heat Pump Fan Delay Time

This numeric field contains the time delay for the heat pump supply air fan to shut off after the compressor cycles off in seconds. This value can be obtained from the manufacturer or the heat pump catalog. Enter a value of zero when the heat pump's fan operating mode is continuous. Suggested value is 60 seconds.

Field: Supplemental Heating Coil Object Type

This is the object type of the supplemental heating coil. The hot water and steam heating coils require specifying plant loop, branches, and connectors objects to support the heating coils, and are placed on the demand side of the plantloop. The valid choices are:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:Water
Coil:Heating:Steam

Field: Supplemental Heating Coil Name

This alpha field contains the identifying name given to the supplemental heating coil, and should match the name specified in the corresponding supplemental heating coil object.

Field: Maximum Supply Air Temperature from Supplemental Heater

This numeric field defines the maximum allowed supply air temperature exiting the heat pump supplemental heating coil in degrees Celsius.

Field: Maximum Outdoor Dry-Bulb Temperature for Supplemental Heater Operation

This numeric field defines the outdoor air dry-bulb temperature in degrees Celsius above which the heat pump supplemental heating coil is disabled. The temperature for this input field must be less than or equal to 21 C. If this input field is left blank, the default value is 21 C.

Field: Outdoor Dry-Bulb Temperature Sensor Node Name

This alpha field specifies the name of the outdoor node which controls the operation of the supplemental heating coil. If this field is left blank, the outdoor temperature is based solely on the weather data. If this field is not blank, the node name specified must also be listed in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an OutdoorAir:NodeList object where the outdoor temperature is taken directly from the weather data.

Field: Fan Placement

This alpha field has two choices: **BlowThrough** or **DrawThrough**. The first choice represents a blow through system where the supply air fan is before the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. The second choice represents a draw through system where the supply fan is between the WaterToAirHeatPump cooling/heating coil and the supplementary heating coil. If this input field is left blank, the default is blow through.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field specifies the name of the supply air fan operating mode schedule. The supply air fan operating mode may vary during the simulation based on time-of-day or with a change of season. Schedule values of 0 denote that the supply air fan and the heating/cooling coil cycle on and off together to meet the heating or cooling load (a.k.a. AUTO fan). Schedule values other than 0 denote that the supply air fan runs continuously while the heating or cooling coil cycles to meet the load. If this field is left blank, the model assumes the supply air fan cycles with the heating or cooling coil throughout the simulation period.

As shown in the example below, correct specification of the water-to-air heat pump requires specification of the following objects in addition to the AirLoopHVAC:UnitaryHeatPump:WaterToAir object:

- On/Off fan
- WaterToAirHeatPump cooling coil
- WaterToAirHeatPump heating coil
- Supplementary heating coil
- Direct air unit for each zone served by the heat pump
- Condenser demand branches

It should be noted that the volumetric air flow rate specified in the direct air unit for the controlling zone should properly reflect the fractional volumetric air flow rate specified in the heat pump object.

Field: Dehumidification Control Type

This alpha input field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. The excess cooling beyond the cooling set point temperature is offset by the supplemental heating coil.

The default is **None**. For **CoolReheat** dehumidification control modes, the maximum humidity setpoint is required. This must be set using a **ZoneControl:Humidistat** object. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate. Supplemental heating coil (supplemental heating coil type and name) is a required input in WaterToAir HeatPumps. When dehumidification control is active the heating and the reheat load due to extra dehumidification are met with supplemental heating coil. The supplemental heating coil capacity must be adequate enough to meet the heating coil load and offset the excess cooling load due to extra dehumidification. The dehumidification control type CoolReheat works only with Coil:Cooling:WaterToAirHeatPump:EquationFit cooling coil type.

AirLoopHVAC:UnitaryHeatPump:WaterToAir Outputs

Energy use reporting for the water-to-air heat pump is documented under the heat pump coil object types:

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation
Coil:Heating:WaterToAirHeatPump:ParameterEstimation
Coil:Cooling:WaterToAirHeatPump:EquationFit
Coil:Heating:WaterToAirHeatPump:EquationFit

The heat pump *demand* as well as the compressor and fan part-load ratios may be obtained with the output variables shown below.

HVAC,Average, Unitary Heat Pump Sensible Cooling Demand[W]
HVAC,Average, Unitary Heat Pump Latent Cooling Demand[W]
HVAC,Average, Unitary Heat Pump Heating Demand[W]

HVAC,Average, Unitary Heat Pump Compressor Part-Load Ratio
HVAC,Average, Unitary Heat Pump Fan Part-Load Ratio
HVAC,Average, Heat Pump Dehumidification Induced Heating Demand Rate [W]

Unitary Heat Pump Sensible Cooling Demand

This output variable is the sensible cooling requested from the zone thermostat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Unitary Heat Pump Latent Cooling Demand

This output variable is the latent cooling requested from the zone humidistat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the heat of vaporization of water at the current zone conditions, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Unitary Heat Pump Heating Demand

This output variable is the sensible heating requested from the zone thermostat in watts. This value is calculated using the unitary heat pump outlet air and zone conditions, the specific heat of the zone air, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Unitary Heat Pump Compressor Part-Load Ratio

This output variable is the ratio of actual load on the unitary system to the unitary system's steady state output. This ratio is based on the nominal capacity of the unit.

Unitary Heat Pump Fan Part-Load Ratio

This output variable is the ratio of actual air mass flow rate through the unitary system to the unitary system's design air mass flow rate (i.e., design volumetric flow rate converted to dry air mass flow rate). For continuous fan operation mode, this variable is always 1.0 when the unitary system is available (based on the availability schedule).

Heat Pump Dehumidification Induced Heating Demand Rate

This output variable is the additional heating demand rate of the supplemental heating coil of a Water-to-Air heat pumps in Watts. This additional heating demand is induced when zone air overshoots the heating setpoint due to extra dehumidification requirement to meet the high humidity setpoint. This value is always positive. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass

The changeover-bypass variable air volume (CBVAV) unitary system is a compound object made up of other components. Each CBVAV system consists of an outdoor air mixer, direct expansion (DX) cooling coil, heating coil, and a supply air fan as shown in the figures below. Zone thermostats and terminal units are required in each zone served by this system. The terminal units are specific to this system type and are either AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat or AirTerminal:SingleDuct:VAV:HeatAndCool>NoReheat. A zone humidistat and single zone max humidity set point manager may also be specified to help control high humidity levels. These individual components are described elsewhere in this document. The CBVAV unitary system object coordinates the operation of these components and is modeled as a type of air loop equipment (Ref. AirLoopHVAC).

Changover-bypass Variable-Air-Volume (CBVAV) Unitary System

Figure 110. Schematic of a CBVAV unitary system (draw through fan placement)

Changover-bypass Variable-Air-Volume (CBVAV) Unitary System

Figure 111. Schematic of a CBVAV unitary system (blow through fan placement)

Links to the CBVAV system's supply air fan, coils, and outdoor air mixer specifications are provided in the object's input syntax. Additional inputs include system and outdoor air flow rates during heating and cooling operation, the priority control mode, and dehumidification

control type. A description of each input field for the CBVAV unitary system compound object is provided below.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a changeover-bypass VAV system. Any reference to this system by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the system operates during a given time period. A schedule value equal to 0 denotes that the system must be off for that time period, and a schedule value greater than 0 denotes that the system is available to operate during that time period. This schedule may be used to completely disable the system (all of its coils and the supply air fan) as required.

Field: System Air Flow Rate During Cooling Operation

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when the DX cooling coil is operating. Values must be greater than 0, or this field is autosizable.

Field: System Air Flow Rate During Heating Operation

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when the heating coil is operating. Values must be greater than 0, or this field is autosizable.

Field: System Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the air flow rate through the system (i.e., through the fan and heating/cooling coils) in cubic meters per second when neither cooling nor heating is required (i.e., the DX cooling coil and heating coil are off but the supply air fan operates). Values must be greater than or equal to zero, or this field is autosizable. This field is only used when the unitary system's supply air fan operating mode is specified as continuous fan operation (Ref. Field: Supply air fan operating mode schedule name). If the system's supply air fan operating mode is specified as continuous fan operation and this value is set to zero or the field is left blank, then the model assumes that the system air flow rate when no heating/cooling is needed is equal to the system air flow rate when the coils were last operating (for cooling operation or heating operation).

Field: Outdoor Air Flow Rate During Cooling Operation

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside_Air_Stream_Node) in cubic meters per second when the DX cooling coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during cooling operating can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the outdoor air flow rate during cooling operation cannot exceed the system air volumetric flow rate during cooling operation.

Field: Outdoor Air Flow Rate During Heating Operation

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside_Air_Stream_Node) in cubic meters per second when the heating coil is operating. Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate during heating operating can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the outdoor air flow rate during heating operation cannot exceed the system air volumetric flow rate during heating operation.

Field: Outdoor Air Flow Rate When No Cooling or Heating is Needed

This numeric field defines the outdoor air flow rate through the system (i.e., through the Outdoor air Mixer's Outside_Air_Stream_Node) in cubic meters per second when neither cooling nor heating is required (i.e., the DX cooling coil and heating coil are off but the supply air fan operates). Values must be greater than or equal to 0, or this field is autosizable. Note that the outdoor air flow rate when no cooling/heating is needed can be changed during the simulation using a multiplier schedule (Ref. Field: Outdoor air volumetric flow rate multiplier schedule name). For any simulation timestep, the outdoor air flow rate when no cooling/heating is needed cannot exceed the system air volumetric flow rate when no cooling/heating is needed. This field is only used when the unitary system's supply air fan operating mode is specified as continuous fan operation (Ref. Field: Supply air fan operating mode schedule name). If the system's supply air fan operating mode is specified as continuous fan operation and this value is set to zero or the field is left blank, then the model assumes that the outdoor air flow rate when no cooling/heating is needed is equal to the outdoor air flow rate when the coils were last operating (for cooling operation [i.e. Outdoor air volumetric flow rate during cooling operation] or heating operation [i.e. Outdoor air volumetric flow rate during heating operation]) and this field is not used.

Field: Outdoor Air Flow Rate Multiplier Schedule Name

This alpha field defines the name of a schedule (ref: Schedule) that contains multipliers for the outdoor air volume flow rates (heating, cooling, no heating/cooling). Schedule values must be from zero to 1. If this field is left blank, then the model assumes that the outdoor air multiplier is 1 for the entire simulation period.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the system draws its inlet air.

Field: Bypass Duct Mixer Node Name

This alpha field defines the name of the HVAC system node where the bypass air mixes with the unitary system's inlet air. This name should match the name of the Return Air Stream Node Name for the OutdoorAir:Mixer associated with this system. This node name must be different from the system's air inlet node name.

Field: Bypass Duct Splitter Node Name

This alpha field defines the name of the HVAC system node where the conditioned air is split into bypass air and supply air leaving the system (e.g., delivered to the terminal units). This splitter air node name should match the outlet node name for the last component (furthest downstream) in this unitary system. For blow through fan placement, the splitter air node is the outlet node of the heating coil. For draw through fan placement, the splitter node is the outlet node of the supply air fan.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the system sends its outlet air.

Field: Outdoor Air Mixer Object Type

This field specifies the type of outdoor air mixer used by this CBVAV unitary system. The outdoor air mixer component is part of the CBVAV unitary compound object. The only available outdoor air mixer type is:

OutdoorAir:Mixer

Field: Outdoor Air Mixer Name

This alpha field defines the name of an outdoor air mixer component that composes part of the CBVAV system. The name of the outdoor air mixer's Return_Air_Stream_Node should match the bypass duct mixer node name, and be different from the CBVAV system's air inlet node name. The Mixed Air Node Name of the outdoor air mixer should be the same as the CBVAV system's supply fan inlet air node (for blow through fan placement) or the system's DX cooling coil inlet node (for draw through fan placement).

Field: Supply Air Fan Object Type

This alpha field defines the type of fan used by this unitary system. The only valid choices are **Fan:OnOff** and **Fan:ConstantVolume**. The input requirements for these fan objects are described elsewhere in this document.

Field: Supply Air Fan Name

This alpha field defines the name of the fan component that composes part of this unitary system. Note that the fan component's maximum flow rate should be greater than or equal to the largest system air volumetric flow rate specified for this unitary system (heating, cooling, and no heating/cooling). In addition, the fan's inlet air node should be the same as the outdoor air mixer's Mixed Air Node (for blow through fan placement) or the heating coil's outlet node (for draw through fan placement). The fan outlet air node should be the same as the DX cooling coil's air inlet node (for blow through fan placement) or the system's bypass duct splitter node (for draw through fan placement).

Field: Supply Air Fan Placement

This alpha field defines the placement of the supply air fan within this unitary system. The only valid choices are **BlowThrough** and **DrawThrough**. With blow through placement, the supply air fan is located immediately upstream of the system's cooling coil. With draw through placement, the supply air fan is located immediately downstream of the heating coil.

Field: Supply Air Fan Operating Mode Schedule Name

This alpha field defines the name of a schedule that specifies the supply air fan operating mode during the simulation. A schedule value of 0 denotes the fan cycles off when no cooling or heating is required, and any other value denotes that the fan runs continuously regardless of the need for heating or cooling. If this field is left blank, the model assumes continuous supply air fan operation for the entire simulation period.

Field: Cooling Coil Object Type

This alpha field defines the type of cooling coil used by this unitary system. There are three valid choices for this field:

Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted
Coil:Cooling:DX:TwoStageWithHumidityControlMode

The input requirements for these cooling coil objects are described elsewhere in this document.

Field: Cooling Coil Name

This alpha field defines the name of the cooling coil used by this unitary system, and this name should match the name specified in the corresponding cooling coil object.

Field: Heating Coil Object Type

This alpha field defines the type of heating coil used by this unitary system. The hot water and steam heating coils require specifying plant loop, branches, and connector objects to support the heating coils, and are placed on the demand side of the plantloop. The valid choices are:

Coil:Heating:Electric
Coil:Heating:Gas
Coil:Heating:DX:SingleSpeed
Coil:Heating:Water
Coil:Heating:Steam

The input requirements for these heating coil objects are described elsewhere in this document.

Field: Heating Coil Name

This alpha field defines the name of the heating coil used by this unitary system, and this name should match the name specified in the corresponding heating coil object.

Field: Priority Control Mode

This choice field defines the cooling or heating priority control mode for the unitary system. Valid choices are:

CoolingPriority
HeatingPriority
ZonePriority

If CoolingPriority is selected, the system operates to meet the cooling load if any zone served by this system (air loop) requires cooling. If no zones require cooling, then the system operates in heating mode if needed. If HeatingPriority is selected, the system operates to meet the heating load if any zone requires heating. If no zones require heating, then the system operates in cooling mode if needed. If ZonePriority is selected, the system operates based on the maximum number of zones requiring either heating or cooling. If the number of zones requiring cooling is greater than the number of zones requiring heating, then the system operates in cooling mode. If the number of zones requiring heating is greater than the number of zones requiring cooling, then the system operates in heating mode. If the number of zones requiring cooling equals the number of zones requiring heating, then the largest combined load (i.e., the sum of the cooling loads for zones requiring cooling compared to the sum of the heating loads for zones that require heating) sets the cooling or heating operating mode for the system during that simulation timestep.

Field: Minimum Outlet Air Temperature During Cooling Operation

This numeric field defines the minimum outlet air temperature leaving the system when the unit is operating to provide cooling. Values are specified in degrees Celsius and must be greater than 0. The default value is 8°C. This value must be less than or equal to the maximum outlet air temperature during heating operation.

Field: Maximum Outlet Air Temperature During Heating Operation

This numeric field defines the maximum outlet air temperature leaving the system when the unit is operating to provide heating. Values are specified in degrees Celsius and must be greater than 0. The default value is 50°C. This value must be greater than or equal to the minimum outlet air temperature during cooling operation.

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

Multimode - activate enhanced dehumidification mode as needed and meet sensible load. This option is used to model DX equipment with a controllable heat exchanger assisting the DX cooling coil for improved dehumidification. It is valid only with cooling coil type = Coil:Cooling:DX:TwoStageWithHumidityControlMode.

CoolReheat - cool beyond the dry-bulb temperature set point as required to meet the high humidity setpoint. It is valid only with cooling coil type = Coil:Cooling:DX:TwoStageWithHumidityControlMode.

The default is **None**. For the other dehumidification control modes, the maximum humidity setpoint on the CBVAV system's air outlet node is used. This must be set using a **ZoneControl:Humidistat** and one of:

- **SetpointManager:SingleZone:Humidity:Maximum**
- **SetpointManager:MultiZone:Humidity:Maximum**
- **SetpointManager:MultiZone:MaximumHumidity:Average**

objects. When extra dehumidification is required, the system may not be able to meet the humidity setpoint if its full capacity is not adequate.

As shown in the example below, correct specification of the CBVAV unitary system requires specification of the following objects in addition to the AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass object:

- 1) outdoor air mixer (OutdoorAir:Mixer)
- 2) fan (Fan:OnOff or Fan:ConstantVolume)
- 3) cooling coil (Coil:Cooling:DX:SingleSpeed, or
CoilSystem:Cooling:DX:HeatExchangerAssisted,
Coil:Cooling:DX:TwoStageWithHumidityControlMode)
- 4) heating coil (Coil:Heating:Gas, Coil:Heating:Electric, or Coil:Heating:DX:SingleSpeed)
- 5) terminal unit for each zone being served by this system (AirTerminal:SingleDuct:VAV:HeatAndCool:Reheat or
AirTerminal:SingleDuct:VAV:HeatAndCool>NoReheat)

Note: The fan, heating coil, cooling coil, and outdoor air mixer must be connected in the air loop according to the configurations shown above (Figure 110 and Figure 111).

Changeover-bypass VAV Total Heating Rate[W]

This output field is the total (enthalpy) heat addition rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are averaged for the timestep being reported.

Changeover-bypass VAV Total Heating Energy[J]

This output field is the total (enthalpy) heat addition of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy addition only) are summed for the timestep being reported.

Changeover-bypass VAV Total Cooling Rate[W]

This output field is the total (enthalpy) heat extraction rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams,

and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are averaged for the timestep being reported.

Changeover-bypass VAV Total Cooling Energy[J]

This output field is the total (enthalpy) heat extraction of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (enthalpy extraction only) are summed for the timestep being reported.

Changeover-bypass VAV Sensible Heating Rate[W]

This output field is the sensible heat addition rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are averaged for the timestep being reported.

Changeover-bypass VAV Sensible Heating Energy[J]

This output field is the sensible heat addition of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (heating only) are summed for the timestep being reported.

Changeover-bypass VAV Sensible Cooling Rate[W]

This output field reports the moist air sensible heat extraction rate of the CBVAV system in Watts. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, and the supply air mass flow rate entering/leaving the system. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are averaged for the timestep being reported.

Changeover-bypass VAV Sensible Cooling Energy[J]

This output field reports the moist air sensible heat extraction of the CBVAV system in Joules over the timestep being reported. This value is calculated using the enthalpy difference of the outlet air and inlet air streams at a constant humidity ratio, the supply air mass flow rate entering/leaving the system, and the HVAC simulation timestep. This value is calculated for each HVAC system timestep being simulated, and the results (cooling only) are summed for the timestep being reported.

Changeover-bypass VAV Latent Heating Rate[W]

This output field is the latent heat addition (humidification) rate of the CBVAV system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are averaged for the timestep being reported.

Changeover-bypass VAV Latent Heating Energy[J]

This output field is the latent heat addition (humidification) of the CBVAV system in Joules over the timestep being reported. This value is calculated as the difference between the total energy and the sensible energy delivered by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat addition only) are summed for the timestep being reported.

Changeover-bypass VAV Latent Cooling Rate[W]

This output field is the latent heat extraction (dehumidification) rate of the CBVAV system in Watts. This value is calculated as the difference between the total energy rate and the sensible energy rate provided by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are averaged for the timestep being reported.

Changeover-bypass VAV Latent Cooling Energy[J]

This output field is the latent heat extraction (dehumidification) of the CBVAV system in Joules over the timestep being reported. This value is calculated as the difference between the total energy and the sensible energy delivered by the system. This value is calculated for each HVAC system timestep being simulated, and the results (latent heat extraction only) are summed for the timestep being reported.

Changeover-bypass VAV Electric Power[W]

This output field is the electricity consumption rate of the CBVAV system in Watts. The consumption includes electricity used by the DX compressor (including crankcase heater), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), and the heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Electric Consumption[J]

This output field is the electricity consumption of the CBVAV system in Joules for the time period being reported. The consumption includes electricity used by the DX compressor (including crankcase heater), fans (indoor supply air fan and the condenser fans associated with the DX coil[s]), and the heating coil (if electric). This value is calculated for each HVAC system timestep being simulated, and the results are summed for the timestep being reported.

Changeover-bypass VAV Fan Part-Load Ratio

This output field is the part-load ratio of the supply air fan, which will be either zero or 1 for each simulation timestep. For this system, the fan will operate continuously for the simulation timestep if the system is available (ref. Field: Availability schedule name) and there is a cooling or heating load to be met (i.e., fan part-load ratio will equal 1). When the system is available but there is no cooling or heating load to be met, the fan will either be off for the entire timestep or on for the entire timestep depending on the supply air fan operating mode schedule (ref. Field: Supply air fan operating mode schedule name). This value is set for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Compressor Part-Load Ratio

This output field is the part-load ratio of the compressor used by the DX coils (cooling and heating). The compressor part-load ratio is defined as the total coil load divided by the coil steady-state capacity (steady-state capacity of first stage for multi-mode coils). This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Bypass Mass Flow Rate[kg/s]

This output field is the mass flow rate of air, in kg/s, being bypassed from the supply air path and blended with the air entering the CBVAV system. This value is calculated for each HVAC system timestep being simulated, and the results are averaged for the timestep being reported.

Changeover-bypass VAV Outlet Air Set Point Temp[C]

This output field is the dry-bulb set point temperature in degrees Celsius. This set point temperature is calculated by the model based on the zone cooling/heating loads calculated by EnergyPlus, and the priority control mode and the dehumidification control type specified for this unitary system. The CBVAV system attempts to achieve the outlet air set point temperature to the extent possible.

Group – Variable Refrigerant Flow Equipment

AirConditioner:VariableRefrigerantFlow

This model simulates a variable-refrigerant-flow (or variable-refrigerant-volume) air-conditioning system. This system type models direct-expansion cooling and/or heating coils configured in a zone terminal unit. For this system type, the zone terminal units are “connected” to a zone via the zone inlet and exhaust nodes. The zone terminal units are identified in a ZoneTerminalUnitList object. And finally, the name of the ZoneTerminalUnitList object is entered as an input to the AirConditioner:VariableRefrigerantFlow object. The Energyplus connection methodology is shown as dashed and greyed arrows in the figure below according to the following rules:

1. The zone inlet and zone exhaust node names are defined in a ZoneHVAC:EquipmentConnections object (bottom of figure).
2. A ZoneHVAC:TerminalUnit:VariableRefrigerantFlow object will identify these zone exhaust and zone inlet node names as the terminal unit's air inlet and air outlet nodes, respectively.
3. All zone terminal units that are connected to the same AirConditioner:VariableRefrigerantFlow object are listed in a ZoneTerminalUnitList object.
4. The name of the ZoneTerminalUnitList object is an input to the AirConditioner:VariableRefrigerantFlow object.
5. The AirConditioner:VariableRefrigerantFlow object is not listed in an AirloopHVAC object and, therefore, can only be simulated if the terminal units are connected to the AirConditioner:VariableRefrigerantFlow object using the ZoneTerminalUnitList.
6. Secondary ZoneHVAC equipment objects may be used in the same zones as the terminal units for other purposes (e.g., code compliance)

The following schematic demonstrates these connection rules.

Figure 112. Variable Refrigerant Flow Schematic

Energyplus object type and object name, and node name relationships are also shown in the following figure to aid in the assembly of this HVAC system type.

Figure 113. Variable Refrigerant Flow Object Links

Field: Heat Pump Name

This alpha field defines a unique user-assigned name for an instance of a variable refrigerant flow heat pump. Any reference to this heat pump will use this name. Since this object is not listed in an AirloopHVAC object, the most likely use of this name would be for reporting purposes.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump operates during a given time period. A schedule value equal to 0 denotes that the heat pump must be off for that time period. A value other than 0 denotes that the heat pump is available to operate during that time period. This schedule may be used to completely disable the heat pump (and all of its terminal units) as required. If this field is blank, the unit is enabled the entire simulation.

Field: Rated Total Cooling Capacity

This numeric field defines the total cooling capacity (sensible + latent) of the heat pump at rated conditions in watts. The cooling capacity must be greater than 0 or set to autosize.

Field: Rated Cooling COP

This numeric field defines the cooling coefficient of performance at rated conditions. The cooling coefficient of performance includes compressor power and condenser fan power. This COP value does not include impacts due to the supply air fan. The nominal heat pump cooling COP must be greater than 0. If this field is left blank, a default coefficient of performance of 3.3 is assumed.

Field: Minimum Outdoor Temperature in Cooling Mode

This numeric field defines the minimum outdoor dry-bulb temperature allowed for cooling operation. Below this temperature, cooling is disabled. If this field is left blank, the default value is -6°C.

Field: Maximum Outdoor Temperature in Cooling Mode

This numeric field defines the maximum outdoor dry-bulb temperature allowed for cooling operation. Above this temperature, cooling is disabled. If this field is left blank, the default value is 43°C.

Field: Cooling Capacity Ratio Modifier Function of Low Temperature Curve Name

This alpha field defines the cooling capacity ratio modifier at low outdoor dry-bulb temperatures. This curve is a bi-quadratic equation using weighted average indoor wet-bulb temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air dry-bulb temperature as the independent variables. This performance curve can be used to describe the cooling capacity ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used). For this system type it is likely that all three of these performance curves will be required. See the Engineering Reference for more discussion on using this input field.

Field: Cooling Capacity Ratio Boundary Curve Name

This alpha field defines the cooling capacity ratio boundary curve name. This curve is a linear, quadratic or cubic curve that defines a change in cooling capacity at a specific condenser entering air dry-bulb temperature as a function of indoor air wet-bulb temperature. This curve is used when the trend in cooling capacity changes dramatically as outdoor temperature changes. If the cooling capacity does not change dramatically with changes in outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

Field: Cooling Capacity Ratio Modifier Function of High Temperature Curve Name

This alpha field defines the cooling capacity ratio modifier at high outdoor temperatures. This curve is a bi-quadratic equation using weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables. This curve is used when the trend in cooling capacity changes dramatically as outdoor temperature changes. If the cooling capacity does not change dramatically with changes in outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

Field: Cooling Energy Input Ratio Modifier Function of Low Temperature Curve Name

This alpha field defines the cooling energy input ratio modifier at low outdoor temperatures. This curve is a bi-quadratic equation with a weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables. This performance curve can be used to describe the cooling energy input ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used). For this system type it is likely that all three of these performance curves will be required. See the Engineering Reference for more discussion on using this input field.

Field: Cooling Energy Input Ratio Boundary Name

This alpha field defines the cooling energy input ratio boundary curve name. This curve is a linear, quadratic or cubic curve that defines a change in cooling energy at a specific condenser entering air dry-bulb temperature as a function of indoor air wet-bulb temperature. This curve is used when the trend in cooling energy changes dramatically as outdoor temperature changes. If the cooling energy does not change dramatically with changes in

outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

Field: Cooling Energy Input Ratio Modifier Function of High Temperature Curve Name

This alpha field defines the cooling energy input ratio modifier at high outdoor temperatures. This curve is a bi-quadratic equation with weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables. This curve is used when the trend in cooling energy changes dramatically as outdoor temperature changes. If the cooling energy does not change dramatically with changes in outdoor conditions, this field may be left blank. See the Engineering Reference for more discussion on using this input field.

Field: Cooling Energy Input Ratio Modifier Function of Low Part-Load Ratio Curve Name

This alpha field defines the cooling energy input ratio modifier (function of part-load ratio when PLR is less than or equal to 1) curve name. This curve is a linear, quadratic or cubic equation with cooling part-load ratio used as the independent variable. The cooling energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the operating part-load ratio is less than or equal to 1.

Field: Cooling Energy Input Ratio Modifier Function of High Part-Load Ratio Curve Name

This alpha field defines the cooling energy input ratio modifier (function of part-load ratio when PLR is greater than 1) curve name. This curve is a linear, quadratic or cubic equation with cooling part-load ratio used as the independent variable. The cooling energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the operating part-load ratio is greater than 1.

Field: Cooling Combination Ratio Correction Factor Curve Name

This alpha field defines the cooling combination ratio (CR) correction factor curve name for combination ratios greater than or equal to 1. The combination ratio is defined as the total rated indoor terminal unit cooling capacity divided by this heat pump's rated total cooling capacity. The curve is a linear, quadratic or cubic equation and uses the minimum value of x in the curve object to determine the maximum part-load ratio which is linearly proportional to capacity (i.e., the minimum value of x [CR] in the curve object must be ≥ 1). The output of this curve provides a multiplier (>1) which is applied to this heat pump's Rated Total Cooling Capacity. Between a combination ratio of 1 and the curve's minimum value of x, the multiplier is linearly interpolated. For combination ratio's less than 1 (i.e., the total indoor terminal unit capacity is less than this heat pump's rated total capacity), capacity is directly proportional to part-load ratio and this curve will not be used.

Field: Cooling Part-Load Fraction Correlation Curve Name

This alpha field defines the cooling part-load fraction correlation curve name. This curve is used to define the cycling losses when the condenser's compressors cycle on and off. The compressor cycles when the cooling part-load ratio is less than the Minimum Heat Pump Part-Load Ratio specified later in this object's inputs.

Field: Rated Total Heating Capacity

This numeric field defines the total heat pump heating capacity at rated conditions in watts. The nominal heat pump heating capacity must be greater than 0 or set to autosize.

Field: Rated Total Heating Capacity Sizing Ratio

This numeric field defines the ratio of heating to cooling capacity. The model assumes that when used, this value will be greater than 1. A similar input is available in the ZoneHVAC:TerminalUnit:VariableRefrigerantFlow object. When the heating capacity is autosized, if this field is non-blank, this ratio is used to scale the heating capacity to the rated total cooling capacity regardless of the value entered in the terminal unit objects. When the

heating capacity is not autosized, the rated total heating capacity will be equal to the sum of the terminal unit heating coil size. If this field is blank and the terminal unit sizing ratio input is also blank, then the heating capacity sizing ratio is assumed to be 1. If this field is not blank and the heating capacity sizing ratio in the terminal unit object(s) is blank, then this ratio also applies to each heating coil. If this field is not blank and the heating capacity sizing ratio in the terminal units is also not blank, then the terminal unit heating coil capacity sizing ratio input applies to each heating coil.

Field: Rated Heating COP

This numeric field defines the heating coefficient of performance at rated conditions. The heating coefficient of performance includes compressor power and condenser fan power. This COP value does not include impacts due to the supply air fan. The nominal heat pump heating COP must be greater than 0. If this field is left blank, a coefficient of performance of 3.4 is assumed.

Field: Minimum Outdoor Temperature in Heating Mode

This numeric field defines the minimum outdoor temperature allowed for heating operation. Below this temperature, heating is disabled. If this field is left blank, the default value is -20°C.

Field: Maximum Outdoor Temperature in Heating Mode

This numeric field defines the maximum outdoor temperature allowed for heating operation. Above this temperature, heating is disabled. If this field is left blank, the default value is 16°C.

Field: Heating Capacity Ratio Modifier Function of Low Temperature Curve Name

This alpha field defines the heating capacity ratio modifier at low temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air dry-bulb or wet-bulb temperature as the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This performance curve can be used to describe the heating capacity ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used). For this system type it is likely that all three of these performance curves will be required. See the Engineering Reference for more discussion on using this input field.

Field: Heating Capacity Ratio Boundary Curve Name

This alpha field defines the heating capacity ratio boundary curve name. This curve is a quadratic or cubic curve that defines a change in heating capacity at a specific condenser entering air dry-bulb or wet-bulb temperature as a function of indoor air dry-bulb temperature. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This curve is used when the trend in heating capacity changes dramatically as outdoor temperature changes. If the heating capacity does not change dramatically with changes in outdoor conditions, this field may be left blank.

Field: Heating Capacity Ratio Modifier Function of High Temperature Curve Name

This alpha field defines the heating capacity ratio modifier at high temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature and condenser entering air dry-bulb or wet-bulb temperature as the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below.

This curve is used when the trend in heating capacity changes dramatically as outdoor temperature changes. If the heating capacity does not change dramatically with changes in outdoor conditions, this field may be left blank.

Field: Heating Energy Input Ratio Modifier Function of Low Temperature Curve Name

This alpha field defines the heating energy input ratio modifier at low temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature and condenser entering air dry-bulb or wet-bulb temperature as the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This performance curve can be used to describe the heating energy input ratio at low outdoor temperatures (i.e., the following two curves are used) or can be used to describe the performance for all outdoor temperatures (i.e., the following two curves are not used).

Field: Heating Energy Input Ratio Boundary Curve Name

This alpha field defines the heating energy input ratio boundary curve name. This curve is a quadratic or cubic curve that defines a change in heating energy at a specific condenser entering air dry-bulb or wet-bulb temperature as a function of indoor air dry-bulb temperature. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This curve is used when the trend in heating energy changes dramatically as outdoor temperature changes. If the heating energy does not change dramatically with changes in outdoor conditions, this field may be left blank.

Field: Heating Energy Input Ratio Modifier Function of High Temperature Curve Name

This alpha field defines the heating energy input ratio modifier at high temperature curve name. This curve is a bi-quadratic equation with a weighted average indoor dry-bulb temperature and condenser entering air dry-bulb or wet-bulb temperature as the independent variables. Since manufacturers may provide performance data using either outdoor dry-bulb or wet-bulb temperatures, either of these temperature types may be used for heating performance curves as specified in the Heating Performance Curve Outdoor Temperature Type input field below. This curve is used when the trend in heating energy changes dramatically as outdoor temperature changes. If the heating energy does not change dramatically with changes in outdoor conditions, this field may be left blank.

Field: Heating Performance Curve Outdoor Temperature Type

This choice field defines the outdoor temperature type used for all performance curves. The valid choices are DryBulbTemperature and WetBulbTemperature. The default value is WetBulbTemperature. Manufacturers will typically provide heating performance data as a function of outdoor air wet-bulb temperatures. This means that the performance (e.g., capacity and energy input ratio) curves will use outdoor wet-bulb temperature as one of the independent variables. At times, manufacturers will only provide performance data as a function of outdoor dry-bulb temperatures. In this case, all performance curves shall be developed using outdoor dry-bulb temperature and this field shall be selected as DryBulbTemperature.

Field: Heating Energy Input Ratio Modifier Function of Low Part-Load Ratio Curve Name

This alpha field defines the heating energy input ratio modifier (function of part-load ratio when PLR is less than or equal to 1) curve name. This curve is a linear, quadratic, or cubic equation with heating part-load ratio used as the independent variable. The heating energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the part-load ratio is less than or equal to 1.

Field: Heating Energy Input Ratio Modifier Function of High Part-Load Ratio Curve Name

This alpha field defines the heating energy input ratio modifier (function of part-load ratio when PLR is greater than 1) curve name. This curve is a linear, quadratic, or cubic equation with heating part-load ratio used as the independent variable. The heating energy input ratio modifier curve is normalized to 1 at a part-load ratio of 1 and is used only when the part-load ratio is greater than 1.

Field: Heating Combination Ratio Correction Factor Curve Name

This alpha field defines the heating combination ratio (CR) correction factor curve name for combination ratios greater than or equal to 1. The combination ratio is defined as the total rated indoor heating capacity divided by the rated heat pump heating capacity. The curve is either quadratic or cubic and uses the minimum value of x in the curve object to determine the maximum part-load ratio which is linearly proportional to capacity (i.e., the minimum value of x in the curve object must be ≥ 1). The output of this curve provides a multiplier (>1) which is applied to the Nominal Heat Pump Heating Capacity. Between a combination ratio of 1 and the curve's minimum value of x, the multiplier is linearly interpolated. For combination ratio's less than 1, capacity is directly proportional to part-load ratio and this curve will not be used. If this field is left blank, the Cooling Combination Ratio Correction factor will be used.

Field: Heating Part-Load Fraction Correlation Curve Name

This alpha field defines the heating part-load fraction correlation curve name. This curve is used to define the cycling losses when the condenser's compressors cycle on and off. The compressor cycles when the indoor to outdoor heating capacity ratio is less than the Minimum Heat Pump Part-Load Ratio specified in the following field.

Field: Minimum Heat Pump Part-Load Ratio

This numeric field specifies the minimum operating part-load ratio (PLR) of the heat pump. When the heat pump operates at a PLR below this value, the heat pump's compressor will cycle to meet the cooling or heating demand. Above this value, the heat pump's compressor operates the entire time step to meet the cooling or heating demand. The minimum value for this field is 0. If this field is left blank, the default value is 0.15. When the heat pump compressor cycles, the previous field is used to determine cycling losses.

Field: Zone Name for Master Thermostat Location

This alpha field defines the name of the zone where the “master” thermostat is located. When the heat pump is connected to multiple zone terminal units, one terminal unit must be selected as the master thermostat. The remaining thermostats are slaves and can operate only in the same mode as the master thermostat.

Field: Master Thermostat Priority Control Type

This choice field determines the logic used to simulate the “master” thermostat. Valid choices are LoadPriority, ZonePriority, ThermostatOffsetPriority, MasterThermostatPriority, and Scheduled. The default value is MasterThermostatPriority. When LoadPriority is selected, the total zone load is used to choose the operating mode as either cooling or heating. When ZonePriority is selected, the number of zones requiring cooling or heating determines the operating mode. When ThermostatOffsetPriority is selected, the zone farthest from the thermostat set point determines the operating mode. The MasterThermostatPriority choice operates the system according the zone load where the master thermostat is located. The heat pump can also be scheduled to operate in either cooling or heating mode. For scheduled operation, a schedule name is entered in the following field.

Field: Thermostat Priority Schedule Name

This alpha field identifies the schedule used when the previous field is set to Scheduled. Schedule values of 0 denote cooling mode while values of 1 denote heating mode. Any other values will force the system off.

Field: Zone Terminal Unit List Name

This alpha field defines the name of the zone terminal unit list. The name specified here should match the name of a valid ZoneTerminalUnitList object. In addition, each name specified in this list should match the name of a valid ZoneHVAC:TerminalUnit:VariableRefrigerantFlow object. All terminal units connected to this heat pump must be listed in this ZoneTerminalUnitList object.

Note: the previous field is designated at the last field necessary to simulate the variable refrigerant flow heat pump. The following fields do not have to be entered, however, piping losses, defrost operation, crankcase heater operation, and basin heater operation will not be modeled. Defaults for fields not entered may also not apply. These remaining fields must be entered if that portion of the model is to be simulated.

Field: Heat Pump Waste Heat Recovery

This choice field defines the configuration of the heat pump refrigeration system. This field is reserved for future use. The only valid choice is No.

Field: Equivalent Piping Length used for Piping Correction Factor in Cooling Mode

This numeric field defines the equivalent pipe length in meters between the farthest terminal unit and the heat pump condenser. This value includes the gas refrigerant line length (for both horizontal and vertical distances), fitting losses, pipe bends, and other connections that contribute to piping losses. This field is used to calculate the piping correction factor in cooling mode. This value defines the head losses due to the pipe length between the farthest terminal unit and the heat pump condenser and impacts the maximum available capacity in cooling mode.

Field: Vertical Height used for Piping Correction Factor

This numeric field defines the vertical pipe height in meters between the highest or lowest terminal unit and the heat pump condenser. This value defines the gravitational losses due to a change in height between the highest (positive value), or lowest (negative value) terminal unit and the heat pump condenser. The distance specified here is applied to the piping correction factor calculation for both cooling and heating. If the distance between the highest terminal unit above the heat pump condenser is greater than the distance between the lowest terminal unit below the condenser enter the difference between the highest and lowest terminal units as a positive distance, otherwise enter this difference as a negative distance. Example: if the distance from the heat pump condenser to the highest terminal unit above the condenser is 10 m and the distance from the heat pump condenser to the lowest terminal unit below the condenser is -15 m, then enter a value of -5 m in this field. This head loss impacts the maximum available capacity in cooling mode.

Field: Piping Correction Factor for Length in Cooling Mode Curve Name

This alpha field defines the linear, quadratic, or cubic curve name used to calculate the piping correction factor for length in cooling mode. Piping losses are a function of piping length. If sufficient piping loss information is available where piping losses are also a function of combination ratio (i.e., in addition to length), a biquadratic performance curve may be used.

Field: Piping Correction Factor for Height in Cooling Mode Coefficient

This numeric field defines the coefficient used to calculate the piping correction factor for height in cooling mode.

Field: Equivalent Piping Length used for Piping Correction Factor in Heating Mode

This numeric field defines the equivalent pipe length in meters between the farthest terminal unit and the heat pump condenser. This value includes the liquid refrigerant line length (for both horizontal and vertical distances), fitting losses, pipe bends, and other connections that

contribute to piping losses. This field is used to calculate the piping correction factor in heating mode. This value defines the head losses due to the pipe length between the farthest terminal unit and the heat pump condenser and impacts the maximum available capacity in heating mode.

Field: Piping Correction Factor for Length in Heating Mode Curve Name

This alpha field defines the linear, quadratic, or cubic curve name used to calculate the piping correction factor for length in heating mode. Piping losses are a function of piping length. If sufficient piping loss information is available where piping losses are also a function of combination ratio (i.e., in addition to length), a biquadratic performance curve may be used.

Field: Piping Correction Factor for Height in Heating Mode Coefficient

This numeric field defines the coefficient used to calculate the piping correction factor for height in heating mode.

Field: Crankcase Heater Power per Compressor

This numeric field defines the electrical power consumed by the crankcase heater in watts for each compressor. This crankcase heater power is consumed when the outdoor temperature is below the maximum outdoor dry-bulb temperature for crankcase heater operation. The minimum value for this field is 0. If this field is left blank, the default value is 33 watts. Crankcase heater electrical consumption is applied only when the compressor is off or is applied during the off cycle when the compressor is cycling below the Minimum Heat Pump Part-Load Ratio. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

Field: Number of Compressors

This numeric field defines the number of compressors in the heat pump condensing unit and is used exclusively to determine the operating characteristics of the crankcase heater. For example, if the number of compressors is 3, one crankcase heater will operate when the heat pump condensing unit's part-load ratio is less than or equal to 0.67 (when the ratio of compressor size to total compressor capacity input is 0.33) and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. Similarly, two crankcase heaters will operate when the heat pump condensing unit's PLR is less than or equal to 0.33 and the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. If the heat pump condensing unit is off, all 3 crankcase heaters will operate if the outdoor temperature is below the maximum outdoor temperature for crankcase heater operation. The minimum value for this field is 1. If this field is left blank, the default value is 2. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

Field: Ratio of Compressor Size to Total Compressor Capacity

This numeric field defines the size of the first stage compressor to the total compressor capacity and is used exclusively for calculating crankcase heater energy. If this field and the previous field are left blank, the default value is 0.5. If this field is left blank and the previous field is not blank, the compressors are assumed to be equally sized. When the number of compressors is greater than 2, the 2nd stage compressor and all additional compressors are assumed to be equally sized. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

Field: Maximum Outdoor Dry-bulb Temperature for Crankcase Heater

This numeric field defines the maximum outdoor temperature, in degrees Celsius, below which the crankcase heater will operate. If this field is left blank, the default value is 0 C. This field is only used to calculate crankcase heater power and has no impact on heat pump performance.

Field: Defrost Strategy

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle. Defrost can be disabled by entering a resistive defrost strategy using a timed defrost control, a 0 defrost time period fraction and a 0 resistive defrost heater capacity in the following inputs fields. This method is used when the Maximum Outdoor Dry-Bulb Temperature for Defrost Operation field value is greater than the expected minimum outdoor dry-bulb temperature simulated in the weather file.

Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value of compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field "Defrost Time Period Fraction" described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field "Maximum Outdoor Dry-bulb Temperature for Defrost Operation" described above. If this input field is left blank, the default defrost control is timed.

Field: Defrost Energy Input Ratio Modifier Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the outdoor air dry-bulb temperature and the weighted average wet-bulb temperature of the air entering the indoor terminal units. The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. The curve is normalized to a value of 1.0 at the rating point conditions.

Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active. For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is 'resistive' (see input field "Defrost Strategy" above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

Field: Maximum Outdoor Dry-bulb Temperature for Defrost Operation

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. If this input field is left blank, the default value is 5 C. Defrost can be completely eliminated by selecting a temperature lower than the minimum expected outdoor temperature found in the weather file.

Field: Condenser Type

This choice field defines the configuration of the heat pump condenser. Valid choices are AirCooled and EvapCooled.

Field: Condenser Inlet Node Name

This alpha field defines the name of the condenser inlet air or water node. For Condenser type = AirCooled, this node name should also be listed in an OutdoorAir:Node or OutdoorAir:NodeList object. If this field is blank, the model assumes an air-cooled condenser and the weather file is used to define the outdoor conditions entering the condenser. If this field is not blank, the node conditions are used to define the outdoor air or inlet water conditions entering the condenser. A node name is typically entered here for air-cooled systems when conditions other than those found in the weather file should be used (ref. OutdoorAir:Node related to height above ground).

Field: Condenser Outlet Node Name

This alpha field defines the name of the condenser outlet water node. This field is only used for water-cooled systems.

Field: Water Condenser Volume Flow Rate

This numeric field defines the condenser water volume flow rate in cubic meters per second. This field is autosizable and only used for water-cooled systems.

Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled and the simulation is calculating heating performance.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = EvapCooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = EvapCooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Cooling Capacity Ratio Modifier Curve (function of temperature) and the Cooling Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb

temperature of the air entering the condenser coil, so the Cooling Capacity and Cooling EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: Evaporative Condenser Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to $0.000144 \text{ m}^3/\text{s}$ per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = AirCooled.

Field: Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = AirCooled.

Field: Supply Water Storage Tank Name

This alpha field defines the name of the water storage tank when an evaporatively-cooled condenser is used.

Field: Basin Heater Capacity

This numeric field contains the capacity of the heat pump's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the heat pump compressor(s) is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature ($^{\circ}\text{C}$) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the heat pump is off. This set point temperature must be greater than or equal to 2°C , and the default value is 2°C if this field is left blank.

Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the heat pump is off.

Field: Fuel Type

This alpha field determines the type of fuel that this variable refrigerant flow system uses. This field has seven choices: Electric, NaturalGas, PropaneGas, Diesel, Gasoline, FuelOil#1, and FuelOil#2. The default is Electric. The use of alternate fuel types assumes an engine drives the variable speed compression system and also accounts for condenser air flow (i.e., a fan attached to the engine provides air flow through the outdoor condenser).

Field: Minimum Outdoor Temperature in Heat Recovery Mode

This numeric field defines the minimum outdoor dry-bulb temperature allowed for heat recovery operation. Below this temperature, heat recovery is disabled. This input must be greater than the larger of the minimum outdoor temperature in cooling or heating mode. If this field is left blank, the default value is the higher of the Minimum Outdoor Temperature in Cooling Mode or Minimum Outdoor Temperature in Heating Mode inputs. This system may still operate in cooling or heating only mode when outdoor temperatures are below the minimum outdoor temperature in heat recovery mode. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes.

Field: Maximum Outdoor Temperature in Heat Recovery Mode

This numeric field defines the maximum outdoor dry-bulb temperature allowed for heat recovery operation. Above this temperature, heat recovery is disabled. This input must be less than the smaller of the maximum outdoor temperature in cooling or heating mode. If this field is left blank, the default value is the lower of the Maximum Outdoor Temperature in Cooling Mode or Maximum Outdoor Temperature in Heating Mode inputs.. This system may still operate in cooling or heating only mode when outdoor temperatures are above the maximum outdoor temperature in heat recovery mode. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes.

Field: Heat Recovery Cooling Capacity Modifier Curve Name

This alpha field defines the cooling capacity modifier when heat recovery mode is active. This modifier is used as a multiplier for available cooling capacity, and when in heat recovery mode, this modifier is usually less than 1. This curve is either a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables or a cubic curve based on part-load ratio. This performance curve can be used to describe the cooling capacity modifier as either a constant (e.g., temperature or part-load ratio term coefficients are 0), a cooling modifier that varies with either indoor temperature and/or outdoor temperature, or part-load ratio (e.g., one or more temperature or part-load ratio term coefficients are 0), or varies with both indoor and outdoor temperatures or part-load ratio (e.g., all temperature or part-load ratio term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 0.9. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in cooling performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode.

Field: Initial Heat Recovery Cooling Capacity Fraction

This numeric field defines the fraction of cooling capacity available when the system transitions from cooling only operation to simultaneous cooling and heating. It is common for the cooling capacity to decrease before the system recovers. If this field is left blank, a default value of 0.5 is used (50% reduction in cooling capacity at the start of heat recovery mode). The system will recover according to the time constant entered in Heat Recovery Cooling Capacity Time Constant input field. If the transition period will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

Field: Heat Recovery Cooling Capacity Time Constant

This numeric field defines the cooling capacity time constant, in hours, used to model the time it takes for the system to change from cooling only operation to simultaneous cooling

and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.083 is used. If the transition period will not be modeled, the Initial Heat Recovery Cooling Capacity Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

Field: Heat Recovery Cooling Energy Modifier Curve Name

This alpha field defines the cooling energy modifier when heat recovery mode is active. This modifier is used as a multiplier for operating cooling energy, and when in heat recovery mode, this modifier is usually greater than 1. This curve is a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables. This performance curve can be used to describe the cooling energy modifier as either a constant (e.g., temperature term coefficients are 0), a cooling energy modifier that varies with indoor and/or outdoor temperatures (e.g., one or more temperature term coefficients are 0), or varies with both indoor and outdoor temperatures (e.g., temperature term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 1.1. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in cooling performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode.

Field: Initial Heat Recovery Cooling Energy Fraction

This numeric field defines the fraction of cooling energy consumed when the system transitions from cooling only operation to simultaneous cooling and heating. It is common for the cooling energy to drop before the system recovers. If this field is left blank, a default value of 1 is used (no change in energy at the start of heat recovery mode). If the transition period will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

Field: Heat Recovery Cooling Energy Time Constant

This numeric field defines the cooling energy time constant, in hours, used to model the time it takes for the system to transition from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Cooling Energy Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from cooling only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

Field: Heat Recovery Heating Capacity Modifier Curve Name

This alpha field defines the heating capacity modifier when heat recovery mode is active. This modifier is used as a multiplier for available heating capacity, and when in heat recovery mode, this modifier is usually less than 1. This curve is a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables. This performance curve can be used to describe the heating capacity modifier as either a constant (e.g., temperature term coefficients are 0), a heating modifier that varies with indoor and/or

outdoor temperatures (e.g., one or more temperature term coefficients are 0), or varies with both indoor and outdoor temperatures (e.g., temperature term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 0.9. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in heating performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode.

Field: Initial Heat Recovery Heating Capacity Fraction

This numeric field defines the fraction of heating capacity available when the system changes from heating only operation to simultaneous heating and cooling. It is common for the heating capacity to decrease before the system recovers. If this field is left blank, a default value of 0.5 is used (50% reduction in heating capacity at the start of heat recovery mode). The system will recover according to the time constant entered in Heat Recovery Heating Capacity Time Constant input field. If the transition period will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

Field: Heat Recovery Heating Capacity Time Constant

This numeric field defines the heating capacity time constant, in hours, used to model the time it takes for the system to transition from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.083 is used. If the transition period will not be modeled, the Initial Heat Recovery Heating Capacity Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

Field: Heat Recovery Heating Energy Modifier Curve Name

This alpha field defines the heating energy modifier when heat recovery mode is active. This modifier is used as a multiplier for operating heating energy, and when in heat recovery mode, this modifier is usually greater than 1. This curve is a bi-quadratic equation using weighted average indoor temperature (i.e., the indoor terminal units weighted average inlet temperatures) and condenser entering air temperature as the independent variables. This performance curve can be used to describe the heating energy modifier as either a constant (e.g., temperature term coefficients are 0), a heating energy modifier that varies with indoor and/or outdoor temperatures (e.g., one or more temperature term coefficients are 0), or varies with both indoor and outdoor temperatures (e.g., temperature term coefficients are non-zero). If this field is left blank, and heat recovery operating mode is selected, the default constant modifier is 1.1. This modifier is applied only when heat recovery mode is active. To model a heat recovery system which has no degradation in heating performance when heat recovery mode is active, or if the degradation is not constant at different operating conditions, a performance curve object must be used. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode.

Field: Initial Heat Recovery Heating Energy Fraction

This numeric field defines the fraction of heating energy consumed when the system changes from heating only operation to simultaneous heating and cooling. It is common for the heating energy to decrease before the system recovers. If this field is left blank, a default value of 0.5

is used (50% reduction in heating energy at the start of heat recovery mode). The system will recovery according to the time constant entered in Heat Recovery Heating Energy Time Constant input field. If the transition period will not be modeled, this input field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

Field: Heat Recovery Heating Energy Time Constant

This numeric field defines the heating energy time constant, in hours, used to model the time it takes for the system to change from cooling only operation to simultaneous cooling and heating. Total response time is defined as 5 time constants. If this field is left blank, a default value of 0.0 is used. If the transition period will not be modeled, the Initial Heat Recovery Heating Energy Fraction field must be set to 1. This input is only used when Heat Pump Waste Heat Recovery is selected as Yes and the system changes from heating only mode to heat recovery mode. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

```

Variable Refrigerant Flow Heat Pump Total Cooling Capacity[W]

This output field is the operating total cooling capacity of the variable refrigerant flow heat pump in Watts. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value should match the sum of the individual zone terminal unit output variables for Zone Terminal Unit Total Cooling Rate.

Variable Refrigerant Flow Heat Pump Total Heating Capacity[W]

This output field is the operating total heating capacity of the variable refrigerant flow heat pump in Watts. The capacity includes any degradation due to defrost mode. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value should match the sum of the individual zone terminal unit output variables for Zone Terminal Unit Total Heating Rate.

Variable Refrigerant Flow Heat Pump Cooling Electric Consumption Rate[W]

This output field is the cooling mode electricity consumption rate of the variable refrigerant flow heat pump in Watts. The consumption includes electricity used by the compressor (including crankcase heater), and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Cooling NaturalGas Consumption Rate).

Variable Refrigerant Flow Heat Pump Cooling Electric Consumption[J]

This output field is the cooling mode electricity consumption of the variable refrigerant flow heat pump in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Report Meter). The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Cooling NaturalGas Consumption). The resource type meter will also be modified to reflect the chosen fuel type (e.g., Resource Type = NaturalGas).

Variable Refrigerant Flow Heat Pump Heating Electric Consumption Rate[W]

This output field is the heating mode electricity consumption rate of the variable refrigerant flow heat pump in Watts. The consumption includes electricity used by the compressor (including crankcase heater), additional energy required for defrost, and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Heating NaturalGas Consumption Rate).

Variable Refrigerant Flow Heat Pump Heating Electric Consumption[J]

This output field is the heating mode electricity consumption of the variable refrigerant flow heat pump in Joules for the time period being reported. The consumption includes electricity used by the compressor (including crankcase heater), additional energy required for defrost, and the condenser fan. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (Ref. Report Meter). The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump Heating NaturalGas Consumption). The resource type meter will also be modified to reflect the chosen fuel type (e.g., Resource Type = NaturalGas).

Variable Refrigerant Flow Heat Pump Cooling COP[]

This is the operating cooling coefficient of performance for the heat pump. This value is calculated using the ratio of Variable Refrigerant Flow Heat Pump Total Cooling Capacity and Variable Refrigerant Flow Heat Pump Cooling Electric Consumption Rate output variables. Crankcase heater (usually 0 in cooling mode), evaporative condenser water pump, and defrost (usually 0 in cooling mode) consumption rate output variables are included in this

calculation. This value is specific to outdoor unit performance in cooling mode, is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Variable Refrigerant Flow Heat Pump Heating COP[]

This is the operating heating coefficient of performance for the heat pump. This value is calculated using the ratio of Variable Refrigerant Flow Heat Pump Total Heating Capacity and Variable Refrigerant Flow Heat Pump Heating Electric Consumption Rate output variables. Crankcase heater, evaporative condenser water pump (usually 0 in heating mode), and defrost consumption rate output variables are included in this calculation. This value is specific to outdoor unit performance in heating mode, is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Variable Refrigerant Flow Heat Pump Operating COP[]

This is the operating coefficient of performance for the heat pump. This value is calculated using the ratio of the total terminal unit coil capacity (cooling plus heating and accounts for piping losses) and total system electric consumption rate (compressor, crankcase heater, evaporative condenser water pump, defrost, and terminal unit parasitic electric consumption rate). This output variable does not include pump power for a water-cooled system. This value is specific to overall system performance, is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Variable Refrigerant Flow Heat Pump Electric Defrost Consumption Rate[W]

This is the electricity consumption rate of the heat pump defrost in Watts when the unit is in defrost mode (timed, reverse-cycle). . The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump NaturalGas Defrost Consumption Rate).

Variable Refrigerant Flow Heat Pump Electric Defrost Consumption[J]

This is the electricity consumption of the heat pump in Joules for the time step being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive). This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (Ref. Report Meter). The choice of an alternate fuel type (see Fuel Type input) will result in a change in the output variable name (e.g., Variable Refrigerant Flow Heat Pump NaturalGas Defrost Consumption). The resource type meter will also be modified to reflect the chosen fuel type (e.g., Resource Type = NaturalGas).

Variable Refrigerant Flow Heat Pump Part Load Ratio

This output field is the part-load ratio of the heat pump condenser. Heat pump part-load ratio is defined as the total coil load divided by the heat pump's maximum available capacity at the current operating conditions. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Variable Refrigerant Flow Heat Pump Runtime Fraction

This output field is the runtime fraction of the heat pump condenser's first stage compressor. Heat pump runtime fraction is defined as the fraction of time the first stage compressor is on during a given time period and includes cycling losses. This value is calculated as the ratio of the Variable Refrigerant Flow Heat Pump Cycling Ratio and the output of the Cooling Part-Load Fraction Correlation Curve object as the specific cycling ratio. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Variable Refrigerant Flow Heat Pump Cycling Ratio

This output field is the cycling ratio of the heat pump condenser's first stage compressor. Heat pump cycling ratio is defined as the fraction of time the first stage compressor is on

during a given time period. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Variable Refrigerant Flow Heat Pump Operating Mode

This output field is an integer representation of the operating mode of the variable refrigerant flow heat pump. The operating mode for cooling mode is indicated by a 1 and heating mode is indicated by a 2. A value of 0 is reported if the heat pump is off. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Variable Refrigerant Flow Heat Pump Inlet Temp [C]

This is the inlet air temperature entering the condenser coil in degrees C. This value can represent the outdoor air dry-bulb temperature, wet-bulb temperature, or somewhere in between from the weather data being used, depending on the value used in the input field "Evaporative Condenser Effectiveness". The temperature reported here is used in the various modifier curves related to temperature (e.g., Total Cooling Capacity Modifier Curve [function of temperature]).

Variable Refrigerant Flow Heat Pump Outlet Temp [C]

This is the condenser coil outlet water temperature in degrees C. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value is only reported for water-cooled systems.

Variable Refrigerant Flow Heat Pump Water Mass Flow Rate [kg/s]

This is the condenser coil outlet water mass flow rate in kilograms per second. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value is only reported for water-cooled systems.

Variable Refrigerant Flow Heat Pump Condenser Heat Transfer Rate [W]

This is the condenser coil heat transfer rate in Watts. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported. This value is only reported for water-cooled systems.

Variable Refrigerant Flow Heat Pump Condenser Heat Transfer [J]

This is the condenser coil heat transfer in Joules. This value is calculated for each HVAC system time step being simulated, and the results are summed for the time step being reported. This value is only reported for water-cooled systems.

Variable Refrigerant Flow Heat Pump Maximum Terminal Unit Cooling Capacity [W]

This output field is the maximum available terminal unit cooling capacity in Watts allowed for the current time step being reported. If the terminal units request more capacity than is actually available from the variable refrigerant flow heat pump, the individual terminal units will be limited to this value. A maximum limit of 1E+20 is reported when there is sufficient capacity available to meet all requests from the terminal units. This output variable easily identifies times when the total terminal unit cooling load exceeds the heat pump's available cooling capacity.

Variable Refrigerant Flow Heat Pump Maximum Terminal Unit Heating Capacity [W]

This output field is the maximum available terminal unit heating capacity in Watts allowed for the current time step being reported. If the terminal units request more capacity than is actually available from the variable refrigerant flow heat pump, the individual terminal units will be limited to this value. A maximum limit of 1E+20 is reported when there is sufficient capacity available to meet all requests from the terminal units. This output variable easily identifies times when the total terminal unit heating load exceeds the heat pump's available heating capacity.

Variable Refrigerant Flow Heat Pump Terminal Unit Cooling Load [W]

This output field is the sum of the terminal unit cooling coil loads in Watts for the current time step being reported. This value is derived directly from the cooling coils and represents the total cooling load on the VRF system after piping losses have been accounted for. The total cooling load will be less than the variable refrigerant flow total cooling capacity reported when piping losses are modeled (i.e., when piping losses are < 1).

Variable Refrigerant Flow Heat Pump Terminal Unit Heating Load [W]

This output field is the sum of the terminal unit heating coil loads in Watts for the current time step being reported. This value is derived directly from the heating coils and represents the total heating load on the VRF system after piping losses have been accounted for. The total heating load will be less than the variable refrigerant flow total heating capacity reported when piping losses are modeled (i.e., when piping losses are < 1).

Variable Refrigerant Flow Heat Pump Crankcase Heater Electric Power [W]

This output field is the average electricity consumption rate of the heat pump's crankcase heaters in Watts for the time step being reported.

Variable Refrigerant Flow Heat Pump Crankcase Heater Electric Consumption [J]

This output field is the electricity consumption rate of the heat pump's crankcase heaters in Joules for the time step being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Variable Refrigerant Flow Heat Pump Evap Condenser Water Consumption [m3]

This output is the amount of water used to evaporatively cool the condenser coil inlet air, in cubic meters. This output is also added to a report meter with Resource Type = Water, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Variable Refrigerant Flow Heat Pump Evap Condenser Pump Electric Power [W]

This is the average electricity consumption rate of the evaporative condenser water pump in Watts for the time step being reported.

Variable Refrigerant Flow Heat Pump Evap Condenser Pump Electric Consumption [J]

This is the electricity consumption rate of the evaporative condenser water pump in Joules for the time step being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Variable Refrigerant Flow Heat Pump Basin Heater Electric Power [W]

This output is the electric consumption rate of the heat pump's basin heater (for evaporatively-cooled condenser type) in Watts. This basin heater only operates when the variable refrigerant flow heat pump's compressor(s) is off and therefore is reported as 0 anytime the compressor operates. If the compressor is cycling (see Variable Refrigerant Flow Heat Pump Cycling Ratio output variable above), the basin heater electric power is proportional to one minus the cycling ratio of the compressor (i.e., the basin heater is on when the compressor is off).

Variable Refrigerant Flow Heat Pump Basin Heater Electric Consumption [J]

This output is the electric consumption of the heat pump's basin heater (for evaporatively-cooled condenser type) in Joules. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Report Meter).

Variable Refrigerant Flow Heat Pump Status Change Multiplier []

This output applies only when heat recovery is used and represents the multiplier used to derate the capacity of the system when transitioning from cooling or heating mode to heat

recovery mode. This value is 1 when derating does not apply (i.e., the system has not recently changed modes to provide heat recovery). Derating during a transition period is applied according to the inputs for Heat Recovery Fraction and Heat Recovery Time Constant. To turn transition derating off, set Heat Recovery Fraction to 1. Refer to the engineering reference document discussion on the variable refrigerant flow heat pump model section for transition from cooling only mode to heat recovery mode for a more detailed description.

ZoneTerminalUnitList

The zone terminal unit list defines the names of the terminal units connected to a single variable refrigerant flow air-conditioning system. The zone terminal unit list is used exclusively in the variable refrigerant flow (VRF) air conditioner object (ref: AirConditioner:VariableRefrigerantFlow). Up to 20 terminal units may be connected to a single VRF outdoor condensing unit. This list is extensible if additional indoor terminal units are required. The name of this zone terminal unit list object is then input into the corresponding variable refrigerant flow air conditioner object. The following figure demonstrates this concept.

Figure 114. Zone Terminal Unit List Diagram

Field: Zone Terminal List Name

This alpha field specifies the name of the zone terminal unit list. This name must be specified in the AirConditioner:VariableRefrigerantFlow object.

Field: Zone Terminal Unit Name <x>

This alpha field defines the name of the zone terminal unit used in a variable refrigerant air conditioner. The zone terminal unit must be connected to a zone using the ZoneHVAC:EquipmentConnections object. The terminal unit air inlet node is the same name as a zone exhaust node. The terminal unit air outlet node is the same name as a zone inlet node. The IDD is supplied with 20 fields for this. The object is extensible and you can change the IDD by adding more fields or, if you are using text editor for your input file, just add to the list of names.

Following is an example input for a ZoneTerminalUnitList object.

```

ZoneTerminalUnitList,

Group – Radiative / Convective Units

This section describes the radiative/convective zone equipment units. The following units are included in this section:

- ZoneHVAC:Baseboard:Convective:Electric
- ZoneHVAC:Baseboard:RadiantConvective:Water
- ZoneHVAC:Baseboard:RadiantConvective:Steam
- ZoneHVAC:Baseboard:RadiantConvective:Electric
- ZoneHVAC:Baseboard:Convective:Water
- ZoneHVAC:HighTemperatureRadiant
- ZoneHVAC:LowTemperatureRadiant:ConstantFlow
- ZoneHVAC:LowTemperatureRadiant:Electric
- ZoneHVAC:LowTemperatureRadiant:VariableFlow

ZoneHVAC:Baseboard:RadiantConvective:Water

The objective of this model is to calculate the convective and radiant heat transfer from water baseboard heaters to the people and the surfaces within a zone so that surface heat balances can take into account the radiant heat transfer to the surfaces and thus enhance the accuracy of thermal comfort predictions within the space. The radiant heat gains are distributed to the surfaces by fractions defined by user input.

Field: Name

A unique user assigned name for an instance of a hot water baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the hot water baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Inlet Node Name

This field is the name of the hot water inlet node for the baseboard heater.

Field: Outlet Node Name

This field is the name of the hot water outlet node for the baseboard heater.

Field: Rated Average Water Temperature

This field is the rated average water temperature for the baseboard heater which is published in the manufacturer's literature in degree Celsius. It typically ranges from 65.56C to 115.36C in the I=B=R rating document while the lowest allowable temperature is 32.22C. The default value is 87.78C. If the user does not enter this field, the default value is assumed.

Field: Rated Water Mass Flow Rate

This field is the rated standard water flow rate in kg/s which is published as part of the manufacturer's literature. It is used by the manufacturers when determining the rated capacity (see next field). The default value is 0.063kg/s. If it is blank or zero, the default values is assumed.

Field: Rated Capacity

This field is the rated water baseboard capacity in watts at a rated water mass flow rate (see previous field). Almost all publications from manufacturers indicate it as W/m (Btuh per linear foot). The user thus must multiply it by the active length of the unit. The active length is available in the literature. Manufacturers are required to publish the difference between active and total length of the unit (I=B=R rating for boilers baseboard radiation, 2009). This field can be autosized by EnergyPlus. If it is blank or zero, autosizing is assumed.

Field: Maximum Water Flow Rate

This field is the maximum water volumetric flow rate in m³/sec. It can be autosized by EnergyPlus.

Field: Convergence Tolerance

This field is the control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For hot water baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq ConvergenceTolerance$$

The default is 0.001.

Field: Fraction Radian

This field specifies what fraction of the power input to the baseboard heater is actually transferred to the space as radiant heat. The fraction should be between 0 and 1. This is the portion of the total power that is modeled as radiation. The portion that is radiant heat transfer from the baseboard heater is distributed to people and specific surfaces using the remaining fields. Note that the sum of the fractions in the remaining fields (people and surfaces) must equal 1.0 so that all the radiant power is distributed properly. For more information on the specification of this parameter, please see the Engineering Reference for EnergyPlus.

Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of radiant portion of heat transfer to the zone from the baseboard heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that although this energy is "radian" it is actually modeled in the zone heat balance as convective energy (like an internal gain). The basic assumption here is that most radiant energy falling on people will most likely be rereleased to the zone air by convection. This is a simplification of reality, but it maintains the overall energy balance.

Field Set: Surface Name, Fraction of Radiant Energy to Surface

The following two items are repeated up to a maximum of 20 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

Field: Surface <x> Name

This field is the name of the first surface to which radiant heat transfer from the baseboard heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

Field: Fraction of Radiant Energy to Surface <x>

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the baseboard heater that is incident on a particular surface. Users should take into account the directionality of baseboard heaters and their location when defining the value for this input field.

Note on Fraction of Radiant Energy Incident on People and to Surfaces

The radiant energy from the baseboard heater is defined by the total energy input to the baseboard heater from the water loop times the fraction radiant field shown above. This radiant energy is distributed to surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions to people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$\text{FractionIndicentOnPeople} + \sum \text{FractionToSurfaces} = 1$$

An example IDF for the water baseboard is shown below.

HVAC, Meter, Baseboard:EnergyTransfer [J]

Baseboard Convective System Impact Rate [W]

This is the actual convective heat addition rate of the baseboard to the zone in Watts. This value includes the heat convected to the zone air from the baseboard unit, the heat radiated to people in the zone from the baseboard unit, and the additional convection from surfaces within the zone that have been heated by radiation from the baseboard unit. This value will be different from (and almost always less than) the next field.

Baseboard Heating Rate [W]

This is the total heat addition rate of the baseboard to the zone it is serving in Watts.

Baseboard Convective Heating Rate [W]

This field reports the rate at which convective heat addition is transferred from the baseboard to the zone in Watts.

Baseboard Radiant Heating Rate [W]

This field reports the rate at which radiant heat addition is transferred from the baseboard to the people and the surfaces within the zone in Watts.

Baseboard Convective System Impact Energy [W]

This is the actual, total convective energy transferred directly and indirectly from the baseboard to the zone it is serving in Joules. Direct convective heat transfer includes the convective portion of the baseboard unit. Indirect convective heat transfer includes heat radiated to people that is then convected to the zone air and heat that is radiated to the surfaces and then convected to the zone air.

Baseboard Heating Energy [J]

This is the total energy of the baseboard to the zone it is serving in Joules over the timestep being reported.

Baseboard Convective Heating Energy [J]

This field reports the amount of convective energy transferred from the baseboard directly to the zone air in Joules.

Baseboard Radiant Heating Energy [J]

This field reports the amount of radiant energy transferred from the baseboard to the zone in Joules.

Baseboard:EnergyTransfer [J]

This meter output variable is the sum of the baseboard heat output from all the baseboards in the HVAC systems in the simulation.

Baseboard Water Mass Flow Rate [kg/s]

This field reports the water mass flow rate at the inlet node of a baseboard unit.

Baseboard Air Mass Flow Rate [kg/s]

This field reports the air mass flow rate at the inlet node of a baseboard unit.

Baseboard Water Inlet Temperature [C]

This field reports the water temperatures at the inlet node of a baseboard unit.

Baseboard Water Outlet Temperature [C]

This field reports the water temperatures at the outlet node of a baseboard unit.

Baseboard Air Inlet Temperature [C]

This field reports the air temperatures at the inlet node of a baseboard unit.

Baseboard Air Outlet Temperature [C]

This field reports the air temperatures at the outlet node of a baseboard unit.

ZoneHVAC:Baseboard:RadiantConvective:Steam

The objective of this model is to calculate the convective and radiant heat transfer from steam baseboard heaters to the people and the surfaces within a zone so that surface heat balances can take into account the radiant heat transfer to the surfaces and thus enhance the accuracy of thermal comfort predictions within the space. The radiant heat gains are distributed to the surfaces by fractions defined by the user. Users are requested to provide degree of sub cooling to estimate the outlet conditions of the condensate.

Field: Name

A unique user assigned name for an instance of a steam baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the steam baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Inlet Node Name

This field is the name of the steam inlet node for the baseboard heater.

Field: Outlet Node Name

This field is the name of the steam outlet node for the baseboard heater.

Field: Degree of SubCooling

This field is the temperature drop of the condensate in the coil of the baseboard heater. The steam condensates in the coil and changes the phase to the water, giving up the latent heat of steam to the air in the steam to air heat exchanger. The condensate due to the phase change then cools by certain degree in the coil, so that this amount of heat is added to the zone. The minimum value is 1.0 Celsius and default is 5.0 Celsius.

Field: Maximum Steam Flow Rate

This field is the maximum steam volumetric flow rate in m³/sec. It can be autosized by EnergyPlus.

Field: Convergence Tolerance

This field is the control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For steam baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq ConvergenceTolerance$$

The default is 0.001.

Field: Fraction Radiant

This field specifies what fraction of the power input to the baseboard heater is actually transferred to the space as radiant heat. The fraction should be between 0 and 1. This is the portion of the total power that is modeled as radiation. The portion that is radiant heat transfer from the baseboard heater is distributed to people and specific surfaces using the remaining fields. Note that the sum of the fractions in the remaining fields (people and surfaces) must equal 1.0 so that all the radiant power is distributed properly.

Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of radiant portion of heat transfer to the zone from the baseboard heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that although this energy is "radiant" it is actually modeled in the zone heat balance as convective energy (like an internal gain). The basic assumption here is that most radiant energy falling on people will most likely be rereleased to the zone air by convection. This is a simplification of reality, but it maintains the overall energy balance.

Field Set: Surface Name, Fraction of Radiant Energy to Surface

The following two items are repeated up to a maximum of 20 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

Field: Surface <x> Name

This field is the name of the first surface to which radiant heat transfer from the baseboard heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

Field: Fraction of Radiant Energy to Surface <x>

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the baseboard heater that is incident on a particular surface. Users should take into account the directionality of baseboard heaters and their location when defining the value for this input field.

Note on Fraction of Radiant Energy Incident on People and to Surfaces

The radiant energy from the baseboard heater is defined by the total energy input to the baseboard heater from the steam loop times the fraction radiant field shown above. This radiant energy is distributed to surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions to people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$\text{FractionIncidentOnPeople} + \sum \text{FractionToSurfaces} = 1$$

Baseboard Convective System Impact Rate [W]

This is the actual convective heat addition rate of the baseboard to the zone in Watts. This value includes the heat convected to the zone air from the baseboard unit, the heat radiated to people in the zone from the baseboard unit, and the additional convection from surfaces within the zone that have been heated by radiation from the baseboard unit. This value will be different from (and almost always less than) the next field.

Baseboard Heating Rate [W]

This is the total heat addition rate of the baseboard to the zone it is serving in Watts.

Baseboard Convective Heating Rate [W]

This field reports the rate at which convective heat addition is transferred from the baseboard to the zone in Watts.

Baseboard Radiant Heating Rate [W]

This field reports the rate at which radiant heat addition is transferred from the baseboard to the people and the surfaces within the zone in Watts.

Baseboard Convective System Impact Energy [J]

This is the actual, total convective energy transferred directly and indirectly from the baseboard to the zone it is serving in Joules. Direct convective heat transfer includes the convective portion of the baseboard unit. Indirect convective heat transfer includes heat radiated to people that is then convected to the zone air and heat that is radiated to the surfaces and then convected to the zone air.

Baseboard Heating Energy [J]

This is the total energy of the baseboard to the zone it is serving in Joules over the time step being reported.

Baseboard Convective Heating Energy [J]

This field reports the amount of convective energy transferred from the baseboard directly to the zone air in Joules.

Baseboard Radian Heating Energy [J]

This field reports the amount of radiant energy transferred from the baseboard to the zone in Joules.

Baseboard:EnergyTransfer [J]

This meter output variable is the sum of the baseboard heat output from all the baseboards in the HVAC systems in the simulation.

Baseboard Steam Mass Flow Rate [kg/s]

This field reports the steam mass flow rate at the inlet node of a baseboard unit.

Baseboard Steam Inlet Temperature [C]

This field reports the steam temperatures at the inlet node of a baseboard unit.

Baseboard Steam Outlet Temperature [C]

This field reports the steam temperatures at the outlet node of a baseboard unit.

ZoneHVAC:Baseboard:RadiantConvective:Electric

The electric baseboard heater is a component in the zone equipment simulation. Heat from this device is radiated to people and surfaces and also convected to the surrounding air. The electric baseboard model includes the impact of the radiant heat addition to people and surfaces so that the thermal comfort and surface heat balances are impacted. The component is controlled to meet any remaining zone load not met by other equipment baseboard operates to meet the remaining zone load and the total electric consumption is calculated by dividing by the efficiency of the baseboard.

Field: Name

A unique user assigned name for an instance of an electric baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Available Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the electric baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit will be off for the hour.

Field: Nominal Capacity

This is the nominal, or maximum capacity, of this electric baseboard unit. This field may be autosized.

Field: Efficiency

This is the overall electrical efficiency of the electric baseboard unit. The zone load met by this unit is divided by the electrical efficiency to obtain the total electric energy used.

Field: Fraction Radiant

This field specifies what fraction of the power input to the baseboard heater is actually transferred to the space as radiant heat. The fraction should be between 0 and 1. This is the portion of the total power that is modeled as radiation. The portion that is radiant heat transfer from the baseboard heater is distributed to people and specific surfaces using the remaining fields. Note that the sum of the fractions in the remaining fields (people and surfaces) must equal 1.0 so that all the radiant power is distributed properly.

Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of the radiant portion of heat transfer to the zone from the baseboard heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that although this energy is "radiant" it is actually modeled in the zone heat balance as a convective energy (like an internal gain). The basic assumption here is that radiant energy falling on people will most likely be rereleased to the zone air by convection. This is a simplification of reality, but it maintains the overall energy balance.

Field Set: Surface Name, Fraction of Radiant Energy to Surface

The following two items are repeated up to a maximum of 20 surface/fraction pairs. At least one surface/fraction pair must appear in an input file. In other words, at least one surface must be identified as a recipient of radiant energy from the baseboard heater.

Field Set: Surface <x> Name

This field is the name of the first surface to which radiant heat transfer from the baseboard heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

Field Set: Fraction of Radiant Energy to Surface <x>

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the baseboard heater that is incident on a particular surface. Users should take into account the directionality of baseboard heaters and their location when defining the value for this input field.

Note on Fraction of Radiant Energy Incident on People and to Surfaces

The radiant energy from the baseboard heater is defined by the total energy input to the baseboard heater times the fraction radiant field shown above. This radiant energy is distributed to surfaces and people using the surface and fraction pairs and the fraction to people input by the user. These fractions to people and surfaces must add up to 1.0. In other words, in an input file, the following relation should be maintained by the user input:

$$\text{FractionIndicentOnPeople} + \sum \text{FractionToSurfaces} = 1$$

Below is an example input for an Electric Baseboard Heater.

Baseboard Convective System Impact Rate [W]

This is the actual convective heat addition rate of the baseboard to the zone in Watts. This value includes the heat convected to the zone air from the baseboard unit, the heat radiated to people in the zone from the baseboard unit, and the additional convection from surfaces within the zone that have been heated by radiation from the baseboard unit. This value will be different from (and almost always less than) the next field.

Baseboard Heating Rate [W]

This is the total heating capacity of the baseboard in Watts.

Baseboard Radiant Heating Rate [W]

This field reports the rate at which radiant heat addition is transferred from the baseboard to the people and the surfaces within the zone in Watts.

Baseboard Convective Heating Rate [W]

This field reports the rate at which convective heat addition is transferred from the baseboard to the zone in Watts.

Baseboard Electric Power [J]

This is the electric power required by the baseboard to the zone it is serving in Watts

Baseboard Convective System Impact Energy [J]

This is the actual convective energy transferred directly and indirectly from the baseboard heater to the zone it is serving in Joules. Direct convective heat transfer includes the convective portion of the baseboard unit. Indirect convective heat transfer includes heat radiated to people that is then convected to the zone air and heat that is radiated to the surfaces and then convected to the zone air.

Baseboard Heating Energy [J]

This is the total energy of the baseboard to the zone it is serving in Joules over the time step being reported.

Baseboard Radiant Heating Energy [J]

This field reports the amount of radiant energy transferred from the baseboard to the zone in Joules.

Baseboard Convective Heating Energy [J]

This field reports the amount of convective energy transferred from the baseboard directly to the zone air in Joules.

Baseboard:Energy Transfer [J]

This meter output variable is the sum of the baseboard heat output from all the electric baseboards in the HVAC systems in the simulation.

Heating:Electricity [J]

This meter output variable is the sum of the electric output from all the electric baseboards in the HVAC systems in the simulation.

ZoneHVAC:Baseboard:Convective:Water

The hot water baseboard heater is a component of zone equipment. The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher heating priority. The control is accomplished by throttling the hot water flow. Input resembles that for the simple heating coil: there is an availability schedule, an overall UA, and a maximum hot water mass flow rate. The unit is connected to a hot water loop (demand side) with an inlet and outlet node. Finally, there is the convergence tolerance, which is the tolerance on how closely the baseboard outlet will meet the zone load. Of course, this tolerance is relative to the zone load.

Field: Name

A unique user assigned name for an instance of a hot water baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Available Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the hot water baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Inlet Node Name

The name of the hot water inlet node for the baseboard heater.

Field: Outlet Node Name

The name of the hot water outlet node for the baseboard heater.

Field: U-Factor Times Area Value

The overall heat transfer coefficient for the baseboard heater in watts per degree Celsius at design conditions. The U-Factor Times Area Value (UA) is used in an NTU - effectiveness calculation. An estimate of the UA can be obtained from:

$$q = UA \times (T_{water,avg} - T_{air,avg})$$

where q is the heat transferred from water to the air in watts; $T_{\text{water, avg}}$ is the average water temperature in degrees C; and $T_{\text{air, avg}}$ is the average air temperature in degrees C. Or the LMTD temperature difference can be used.

Field: Maximum Water Flow Rate

The maximum hot water volumetric flow rate in m³/sec.

Field Convergence Tolerance

The control tolerance for the unit heating output. The unit is controlled by matching the unit output to the zone demand. For hot water baseboards, the model must be numerically inverted to obtain a specified output. The convergence tolerance is the error tolerance used to terminate the numerical inversion procedure. Basically this is the fraction:

$$\frac{|(Q_{bb,out} - Q_{ZoneLoad})|}{Q_{ZoneLoad}} \leq \text{ConvergenceTolerance}$$

The default is 0.001.

An example IDF for the hot water convective baseboard is shown below.

```

ZoneHVAC:Baseboard:Convective:Water Outputs

HVAC,Average,Baseboard Heating Rate[W]
HVAC,Sum,Baseboard Heating Energy[J]
HVAC,Meter,Baseboard:EnergyTransfer [J]

Baseboard Heating Rate[W]

This is the heat addition rate of the convective baseboard to the zone it is serving in Watts.

Baseboard Heating Energy[J]

This is the heat addition of the convective baseboard to the zone it is serving in Joules over the timestep being reported.

Baseboard:EnergyTransfer [J]

This meter output variable is the sum of the baseboard heat output from all the baseboards in the HVAC systems in the simulation.

Baseboard Water Mass Flow Rate [kg/s]

This field reports the water mass flow rate at the inlet node of a baseboard unit.

Baseboard Air Mass Flow Rate [kg/s]

This field reports the air mass flow rate at the inlet node of a baseboard unit.

Baseboard Water Inlet Temperature [C]

This field reports the water temperatures at the inlet node of a baseboard unit.

Baseboard Water Outlet Temperature [C]

This field reports the water temperatures at the outlet node of a baseboard unit.

Baseboard Air Inlet Temperature [C]

This field reports the air temperatures at the inlet node of a baseboard unit.

Baseboard Air Outlet Temperature [C]

This field reports the air temperatures at the outlet node of a baseboard unit.

ZoneHVAC:Baseboard:Convective:Electric

The electric baseboard heater is a component in the zone equipment simulation. The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher heating priority. The control is accomplished by taking the remaining zone load and dividing by the efficiency of the baseboard.

Field: Name

A unique user assigned name for an instance of a electric baseboard heater unit. Any reference to this unit by another object will use this name.

Field: Available Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the electric baseboard heater unit can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Nominal Capacity

This is the nominal, or maximum capacity, of this electric baseboard unit.

Field: Efficiency

This is the overall electrical efficiency of the electric baseboard. The zone load met by this unit is divided by the electrical efficiency to obtain the total electric energy used.

An example IDF for the electric convective baseboard is shown below.

```
ZoneHVAC:Baseboard:Convective:Electric,
  Zone1Baseboard, !- Baseboard Name

Baseboard Heating Rate[W]

This is the heat addition rate of the electric convective baseboard to the zone it is serving in Watts.

Baseboard Heating Energy[J]

This is the heat addition of the convective baseboard to the zone it is serving in Joules over the timestep being reported.

Baseboard:EnergyTransfer [J]

This meter output variable is the sum of the baseboard heat output from all the baseboards in the HVAC systems in the simulation regardless of Energy input.

Baseboard Electric Consumption [J]

This is the total electric consumption of the baseboard for the zone it is serving in Joules over the timestep being reported.

Baseboard Electric Power [W]

This is the electric power required by the baseboard to the zone it is serving in Watts.

Heating:Electricity [J]

This meter output variable is the sum of the electric output from all the electric baseboards in the HVAC systems in the simulation.

ZoneHVAC:LowTemperatureRadiant:VariableFlow

This low temperature radiant system (hydronic) is a component of zone equipment that is intended to model any “radiant system” where water is used to supply/remove energy to/from a building surface (wall, ceiling, or floor). The component is controlled to meet any remaining zone load not met by other equipment in the zone that have higher priority. The control is accomplished by throttling the hot or chilled water flow to the unit. Note that this system will only control based on the radiant system controls defined by this input syntax and not via a zone thermostat such as is used for forced air systems. Note also that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

This model covers a wide range of low temperature radiant systems: heating and/or cooling, panel or embedded pipes, etc. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use electric resistance heating should also be defined using separate input syntax (ref: ZoneHVAC:LowTemperatureRadiant:Electric).

Field: Name

This field is an unique user assigned name for an instance of a hydronic low temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the hydronic low temperature radiant system can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the hydronic low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: BuildingSurface) or surface list (Ref: ZoneHVAC:LowTemperatureRadiant:SurfaceGroup) in which the hydronic tubing is

embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (e.g., BuildingSurface:Detailed) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Hydronic Tubing Inside Diameter

This field is the inside diameter of the tubes through which water is circulated for the system being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the water to the inside surface of the hydronic tubing.

Field: Hydronic Tubing Length

This field is the total length of pipe embedded in the surface named above in the surface name field. The length of the tube should be entered in meters and is used to determine the effectiveness of heat transfer from the fluid being circulated through the tubes and the tube/surface. Longer tubing lengths result in more heat will be transferred to/from the radiant surface to the circulating fluid. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values.

Field: Temperature Control Type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the hydronic radiant system. The temperature denoted in the setpoint schedule can refer to one of five different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, or the outdoor wet-bulb temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature
MeanRadiantTemperature
OperativeTemperature
outdoorDryBulbTemperature
outdoorWetBulbTemperature

Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature. If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information.

Field: Maximum Hot Water Flow

This field is the maximum flow rate of hot water through the radiant system in m³/sec. The controls for the radiant system will vary the flow rate of hot water through the surface using zero flow and the maximum flow rate specified in this field as the lower and upper bounds, respectively. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values.

Field: Heating Water Inlet Node Name

This field contains the name of the hot water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating Water Outlet Node Name

This field contains the name of the hot water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating Control Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero flow rate up to the maximum defined by the maximum hot water flow rate field described above. The throttling range parameter is used in conjunction with the control temperature to define the response of the system to various zone conditions. The heating control temperature schedule specifies the “setpoint” temperature where the flow rate to the system is at half of the maximum flow rate. For example, if the heating control temperature setpoint is currently 15°C and the heating throttling range is 2°C, the water flow rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, ODB, or OWB; see control type field above) is at or above 16°C and the maximum flow rate when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the flow rate to the radiant system is varied linearly.

Field: Heating Control Temperature Schedule Name

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating control throttling range), it will define whether or not the system is running and the current flow rate. Water flow rate to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum heating flow rate parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. The control of the radiant system is based solely on the heating control temperature schedule, the cooling control temperature schedule (see below), and the control temperature type listed above. The radiant system will not use any zone thermostat that might be used by other systems serving the zone in which the radiant system resides.

Field: Maximum Cold Water Flow

This field is the maximum flow rate of cold water through the radiant system in m³/sec. The controls for the radiant system will vary the flow rate of cold water through the surface using zero flow and the maximum flow rate specified in this field as the lower and upper bounds, respectively. Note that this field is optional and not required for a heating only system. Note also that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values.

Field: Cooling Water Inlet Node Name

This field contains the name of the cold water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling Water Outlet Node Name

This field contains the name of the cold water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling Control Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero flow rate up to the maximum defined by the maximum cold water

flow rate field described above. The throttling range parameter is used in conjunction with the control temperature to define the response of the system to various zone conditions. The cooling control temperature schedule specifies the “setpoint” temperature where the flow rate to the system is at half of the maximum flow rate. For example, if the cooling control temperature setpoint is currently 25°C and the cooling throttling range is 2°C, the water flow rate to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, ODB, or OWB; see control type field above) is at or below 24°C and the maximum flow rate when the controlling temperature is at or above 26°C. This represents a throttling range of 2°C around the setpoint of 25°C. In between 24°C and 26°C, the flow rate to the radiant system is varied linearly.

Field: Cooling Control Temperature Schedule Name

This field specifies the cooling setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (cooling control throttling range), it will define whether or not the system is running and the current flow rate. Water flow rate to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum cooling flow rate parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for cooling. The control of the radiant system is based solely on the heating control temperature schedule listed above, the cooling control temperature schedule, and the control temperature type listed above. The radiant system will not use any zone thermostat that might be used by other systems serving the zone in which the radiant system resides.

Field: Condensation Control Type

When radiant systems do cooling, there is the possibility that condensation will occur on the surface that is being cooled. This is due to the fact that the surface temperature may drop below the dew-point temperature of the space. When this occurs, condensation on the surface will occur. In EnergyPlus, users have several options for handling this situation including: Off and SimpleOff. When the user chooses the Off option, EnergyPlus will not do anything other than produce a warning message when condensation is predicted to occur. The program will simply continue on; no moisture will be removed from the zone air and there will be no adjustment of the surface temperature as a result of the condensation. When the user chooses the SimpleOff option, the program will predict cases where condensation will occur and shut-off the radiant system to avoid this situation. With this option, the users also have the opportunity to adjust when the system will shut down. This is specified with the next parameter (field: condensation differential parameter). This parameter is optional and EnergyPlus will use the SimpleOff strategy when this parameter is not specified.

Field: Condensation Control Dewpoint Offset

This optional parameter is only valid with the SimpleOff condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed surface temperature to which the surface can drop before the radiant system shuts down in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down when the surface temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down when the surface is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down when the surface temperature is the number of degrees Celsius below the dew-point temperature. While not recommended, this strategy allows the user to simulate a situation where small amounts of condensation are tolerable.

An example IDF with a hydronic low temperature radiant system is shown below.

HVAC,Sum,Hydronic Low Temp Radiant Time Condensation Occurring[s]

Hydronic Low Temp Radiant Heating Rate[W]

This field reports the heating input rate to the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

Hydronic Low Temp Radiant Heating Energy[J]

This field reports the heating input to the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Hydronic Low Temp Radiant Cooling Rate[W]

This field reports the cooling input rate to the low temperature radiant system in Watts. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

Hydronic Low Temp Radiant Cooling Energy[J]

This field reports the cooling input to the low temperature radiant system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Hydronic Low Temp Radiant Water Mass Flow Rate[kg/s]

This field reports the mass flow rate of water through the low temperature radiant system in kilograms per second.

Hydronic Low Temp Radiant Water Inlet Temp[C]

This field reports the temperature of water entering the low temperature radiant system in Celsius.

Hydronic Low Temp Radiant Water Outlet Temp[C]

This field reports the temperature of water leaving the low temperature radiant system in Celsius.

Hydronic Low Temp Radiant Time Condensation Occurring[s]

This field reports the amount of time when condensation is occurring. When using the Off condensation control, this simply reports the amount of time when condensation occurs. When using the SimpleOff condensation control, this indicates the amount of time when the system has been shut off because of the potential danger of condensation.

ZoneHVAC:LowTemperatureRadiant:ConstantFlow

This low temperature radiant system (hydronic) is a component of zone equipment that is intended to model any “radiant system” where water is used to supply/remove energy to/from a building surface (wall, ceiling, or floor). The component is controlled via control schedules as described in the syntax below and does not require a zone thermostat. Note that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

The constant flow system differs from the hydronic system describe above in what it controls. The hydronic system varies the flow rate through the radiant system based on some control temperature. The constant flow system keeps flow rate constant via a local circulation pump and varies the water temperature that is sent to the radiant system. This is accomplished with a mixing valve that is controlled by a sensor. This model covers a wide range of low temperature radiant systems: heating and/or cooling, panel or embedded pipes, etc. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use electric resistance heating should also be defined using separate input syntax (ref: ZoneHVAC:LowTemperatureRadiant:Electric). Low temperature radiant systems that vary the flow rate through the radiant system should also be defined using separate input syntax (ref: ZoneHVAC:LowTemperatureRadiant:VariableFlow)

One of the other differences between this model and the variable flow hydronic radiant system is that the constant flow radiant system has a built-in local secondary loop. It will recirculate flow coming out of the system and mix this with flow from the loop to arrive at the desired inlet temperature to the radiant system (note that this model has the temperature sensor AFTER the pump to insure proper inlet temperature to the radiant system). The local loop also contains a pump which is assumed to be upstream of the radiant system and after the mixing valve. So, the local loop can have some recirculation. The flow from the main loop may also bypass the radiant system if more than enough flow is available and the main loop is also a constant flow system.

Field: Name

This field is an unique user assigned name for an instance of a constant flow low temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the constant flow low temperature radiant system can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the constant flow low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: BuildingSurface:Detailed) or surface list (Ref: ZoneHVAC:LowTemperatureRadiant:SurfaceGroup) in which the hydronic tubing is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (BuildingSurface:Detailed) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Hydronic Tubing Inside Diameter

This field is the inside diameter of the tubes through which water is circulated for the system being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the water to the inside surface of the hydronic tubing.

Field: Hydronic Tubing Length

This field is the total length of pipe embedded in the surface named above in the surface name field. The length of the tube should be entered in meters and is used to determine the effectiveness of heat transfer from the fluid being circulated through the tubes and the tube/surface. Longer tubing lengths result in more heat being transferred to/from the radiant surface to the circulating fluid.

Field: Temperature Control Type

This field specifies along with setpoint (control) and water schedules how the user wishes to control the constant flow radiant system. The temperature denoted in the setpoint schedule can refer to one of five different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, or the outdoor wet-bulb temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature
MeanRadiantTemperature
OperativeTemperature
OutdoorDryBulbTemperature
OutdoorWetBulbTemperature

Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature. If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information.

Field: Rated Flow Rate

This field is the maximum flow rate of water through the radiant system in m³/sec. This flow rate is held constant by the local component pump, but the user has the option of varying this flow rate via a schedule (see next input field). The constant flow system will accept this flow rate and control the inlet temperature based on the control and water temperature schedules defined below.

Field: Pump Flow Rate Schedule Name

This field modifies the maximum flow rate of water through the radiant system in m³/sec. This input is “optional”. If the user does not enter a schedule, the flow rate through the radiant system is assumed to be constant during all hours that it is operating based on the value entered in the previous input field. Note that the values for this schedule must be between zero and one. The values in this schedule are multipliers on the previous field – Rated Flow Rate.

Field: Rated Pump Head

This numeric field contains the pump's rated head in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump's rated power consumption in Watts.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Heating Water Inlet Node Name

This field contains the name of the hot water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating Water Outlet Node Name

This field contains the name of the hot water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a heating coil.

Field: Heating High Water Temperature Schedule Name

This field specifies the high water temperature in degrees Celsius for the temperature control of a constant flow radiant heating system. Water and control temperatures for heating work together to provide a linear function that determines the water temperature sent to the radiant system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the system will be turned off and the water mass flow rate will be zero. If the control temperature is below the low temperature, then the inlet water temperature is set to the high water temperature. If the control temperature is between the high and low value, then the inlet water temperature is linearly interpolated between the low and high water temperature values. For more information and a graph of how the water and control schedules affect the system operation, please consult the Engineering Reference document.

Field: Heating Low Water Temperature Schedule Name

This field specifies the low water temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

Field: Heating High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

Field: Heating Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a constant flow heating radiant system. For more information on its interpretation, see Heating High Water Temperature Schedule above.

Field: Cooling Water Inlet Node Name

This field contains the name of the cold water inlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling Water Outlet Node Name

This field contains the name of the cold water outlet node to the radiant system. Note that this node name must also show up in the branch description when defining the plant demand side network in a manner identical to defining a cooling coil. As with the maximum cold water flow rate, this field is optional and not required for a heating only system.

Field: Cooling High Water Temperature Schedule Name

This field specifies the high water temperature in degrees Celsius for the temperature control of a constant flow radiant cooling system. Water and control temperatures for heating work together to provide a linear function that determines the water temperature sent to the radiant system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet water temperature is set to the low water temperature. If the control temperature is below the low temperature, then system will be turned off and the water mass flow rate will be zero. If the control temperature is between the high and low value, then the inlet water temperature is linearly interpolated between the low and high water temperature values. For more information and a graph of how the water and control schedules affect the system operation, please consult the Engineering Reference document.

Field: Cooling Low Water Temperature Schedule Name

This field specifies the low water temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

Field: Cooling High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

Field: Cooling Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Water Temperature Schedule above.

Field: Condensation Control Type

When radiant systems do cooling, there is the possibility that condensation will occur on the surface that is being cooled. This is due to the fact that the surface temperature may drop below the dew-point temperature of the space. When this occurs, condensation on the surface will occur. In EnergyPlus, users have several options for handling this situation including: Off and SimpleOff. When the user chooses the Off option, EnergyPlus will not do anything other than produce a warning message when condensation is predicted to occur. The program will simply continue on; no moisture will be removed from the zone air and there will be no adjustment of the surface temperature as a result of the condensation. When the

user chooses the SimpleOff option, the program will predict cases where condensation will occur and shut-off the radiant system to avoid this situation. With this option, the users also have the opportunity to adjust when the system will shut down. This is specified with the next parameter (field: condensation differential parameter). This parameter is optional and EnergyPlus will use the SimpleOff strategy when this parameter is not specified.

Field: Condensation Control Dewpoint Offset

This optional parameter is only valid with the SimpleOff condensation handling algorithm (see previous input parameter). It establishes the difference between the calculated dew-point temperature of the space and the allowed surface temperature to which the surface can drop before the radiant system shuts down in degrees Celsius. This parameter can be any positive, negative, or zero value. When this parameter is zero, the radiant system will shut down when the surface temperature drops to the dew-point temperature or below. When this parameter is positive, the radiant system will shut down when the surface is the number of degrees Celsius above the dew-point temperature. This allows some extra safety to avoid condensation. When this parameter is negative, the radiant system will shut down when the surface temperature is the number of degrees Celsius below the dew-point temperature. While not recommended, this strategy allows the user to simulate a situation where small amounts of condensation are tolerable.

HVAC,Sum,Constant Flow Low Temp Radiant Time Condensation Occurring[s]

Constant Flow Low Temp Radiant Heating Rate[W]

This field reports the heating input rate to the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

Constant Flow Low Temp Radiant Heating Energy[J]

This field reports the heating input to the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Constant Flow Low Temp Radiant Cooling Rate[W]

This field reports the cooling input rate to the low temperature radiant system in Watts. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

Constant Flow Low Temp Radiant Cooling Energy[J]

This field reports the cooling input to the low temperature radiant system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Constant Flow Low Temp Radiant Water Mass Flow Rate[kg/s]

This field reports the mass flow rate of water through the low temperature radiant system in kilograms per second. This should be identical to the pump flow rate for the system.

Constant Flow Low Temp Radiant Injection Mass Flow Rate[kg/s]

This field reports the mass flow rate of water that is injected into the radiant system from the main loop. A valve will control the injection and recirculation mass flow rates (see next field) to match the temperature controls specified by the user and dictated by the current simulation conditions.

Constant Flow Low Temp Radiant Recirculation Mass Flow Rate[kg/s]

This field reports the mass flow rate of water that is recirculated from the radiant system outlet and mixed with the injection flow from the main loop. A valve will control the injection and recirculation mass flow rates (see next field) to match the temperature controls specified by the user and dictated by the current simulation conditions.

Constant Flow Low Temp Radiant Water Inlet Temp[C]

This field reports the temperature of water entering the low temperature radiant system in Celsius. This may differ from the inlet node temperature for the component since this component has its own local secondary loop.

Constant Flow Low Temp Radiant Water Outlet Temp[C]

This field reports the temperature of water leaving the low temperature radiant system in Celsius. This may differ from the outlet node temperature for the component since this component has its own local secondary loop.

Constant Flow Low Temp Pump Water Inlet Temp[C]

This field reports the temperature of water entering the low temperature radiant system pump in Celsius. This may differ from the inlet node temperature for the component since this

component has its own local secondary loop. It is assumed that the pump is upstream of the radiant system.

Constant Flow Low Temp Pump Electric Power[W]

This field reports the rate of electric power consumption for the pump which supplies flow to the constant flow radiant system in Watts.

Constant Flow Low Temp Pump Electric Consumption[J]

This field reports the electric power consumption for the pump which supplies flow to the constant flow radiant system in Joules.

Constant Flow Low Temp Radiant Pump Water Mass Flow[kg/s]

This field reports the mass flow rate of water through the low temperature radiant system pump in kilograms per second. This should be identical to the flow rate for the system.

Constant Flow Low Temp Pump Heat to Fluid[W]

This field reports the rate at which heat is added to the fluid stream as it passes through the pump in Watts. This heat is reflected in the radiant system inlet temperature which will be different from the pump inlet temperature if this field has a non-zero value.

Constant Flow Low Temp Pump Heat to Fluid Energy[J]

This field reports the amount of heat energy added to the fluid stream as it passes through the pump in Joules. This heat is reflected in the radiant system inlet temperature which will be different from the pump inlet temperature if this field has a non-zero value.

Constant Flow Low Temp Radiant Time Condensation Occurring[s]

This field reports the amount of time when condensation is occurring. When using the Off condensation control, this simply reports the amount of time when condensation occurs. When using the SimpleOff condensation control, this indicates the amount of time when the system has been shut off because of the potential danger of condensation.

ZoneHVAC:LowTemperatureRadiant:Electric

This low temperature radiant system (electric) is a component of zone equipment that is intended to model any “radiant system” where electric resistance heating is used to supply energy (heat) to a building surface (wall, ceiling, or floor). The component is controlled by the radiant system controls that are defined in the syntax below and this control does not require the use of a zone thermostat unless the unit is being autosized. Note also that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

The control is accomplished by varying the electrical power supplied to the unit. This model covers either a radiant panel system or wires embedded in entire walls, floors, or ceilings. It is not intended to simulate high temperature electric or gas radiant heaters. Those devices will be handled by a separate model and different input syntax. Low temperature radiant systems that use water flowing through tubes to provide heat to the system should also be defined using separate input syntax (ref: Low Temp Radiant System:Hydronic).

Field: Name

This field is an unique user assigned name for an instance of an electric low temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the electric low temperature radiant system can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the electric low temperature radiant system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the radiant system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: BuildingSurface) or surface list (Ref: ZoneHVAC:LowTemperatureRadiant:SurfaceGroup) in which the hydronic tubing is embedded/contained. This specification attaches the source or sink from the radiant system to a particular surface and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (e.g. BuildingSurface:Detailed) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Maximum Electrical Power to Panel

This field is the maximum amount of electrical energy that can be converted to heat in this particular radiant system in Watts. The controls for the radiant system will vary the amount of power supplied to the surface between zero input and the maximum power specified in this field as the lower and upper bounds, respectively. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values.

Field: Temperature Control Type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the low temperature electric radiant system. The temperature denoted in the setpoint schedule can refer to one of three different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the outdoor dry-bulb temperature, or the outdoor wet-bulb temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature
MeanRadiantTemperature
OperativeTemperature
OutdoorDryBulbTemperature
OutdoorWetBulbTemperature

Operative temperature for radiant system controls is the average of Mean Air Temperature and Mean Radiant Temperature. If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the throttling range and control temperature schedule fields below for more information.

Field: Heating Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero heat input via the electric resistance wires up to the maximum defined by the maximum electrical power field described above. The throttling range

parameter is used in conjunction with the control temperature (see below) to define the response of the system to various zone conditions. The heating control temperature schedule specifies the “setpoint” temperature where the power input to the system is at half of the maximum power input. For example, if the heating control temperature setpoint is currently 15°C and the heating throttling range is 2°C, the electrical power supplied to the radiant system will be zero when the controlling temperature (MAT, MRT, Operative Temperature, ODB, or OWB; see control type field above) is at or above 16°C and the maximum power input when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the power input to the radiant system is varied linearly.

Field: Heating Setpoint Temperature Schedule Name

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating throttling range), it will define whether or not the system is running and the current power input to the radiant surface. Power input to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum electrical power parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. In addition, this schedule may be different than the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

An example IDF with an electric low temperature radiant system is shown below.

```

    MeanAirTemperature, ! control type (control on mean air temperature)
    2.0, ! heating throttling range (in C)
    Radiant Heating Setpoints ; ! heating setpoint temperatures
```

ZoneHVAC:LowTemperatureRadiant:Electric Outputs

HVAC,Average, Electric Low Temp Radiant Electric Power[W]
HVAC,Sum, Electric Low Temp Radiant Electric Consumption[J]

Electric Low Temp Radiant Electric Power [W]

This field reports the rate at which electric energy is “burned” in the low temperature radiant system in Watts. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions and the control scheme defined in the user input.

Electric Low Temp Radiant Electric Consumption [J]

This field reports the amount of electric energy “burned” in the low temperature radiant system in Joules. This is the heat source to the surface that is defined as the radiant system. The heating rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

ZoneHVAC:LowTemperatureRadiant:SurfaceGroup

A low temperature radiant system (hydronic or electric) may consist of multiple active surfaces that are serving to condition the space. Surfaces that act serially can be specified as multiple radiant systems using the standard radiant system input described above. However, if the multiple surfaces act in parallel, the Radiant System Surface Group input line is used to specify which surfaces are acting in a coordinated fashion and how flow rate is split between the surfaces. This list of surfaces (the name it is assigned) replaces the name of a single

surface in the radiant system input described above. Note that all of the surfaces within a single list must be a part of the same zone and that the zone of these surfaces must also match the zone the radiant system is attempting to condition.

Field: Name

This field is an unique user assigned name for the list of surfaces that are acting in coordination with one another. Any reference to this list by a radiant system will use this name.

Field Set: Surface Name, Flow Fraction to Surface

The pairs of Surface Name, Flow Fraction to Surface are used in several objects. There can be up to 10 specified. The object is extensible so more can be added.

Field: Surface <x> Name

This field is the name of a surface in the zone being conditioned by the radiant system. Only base surfaces (walls, roofs, floors) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Flow Fraction for Surface <x>

This field is the fraction of the total radiant system flow rate that is being sent to this particular surface. Note that the Surface Name/Surface Flow Fraction pair can be repeated up to 10 times. Flow rate fractions must sum to unity, otherwise the program will not accept the input as valid.

An example IDF with an electric low temperature radiant system is shown below.

```
ZoneHVAC:LowTemperatureRadiant:SurfaceGroup,
  Zone 1 Radiant Surfaces, !- name of surface list
    Zn001:Flr001,           !- Surface name 1
    0.75,                  !- Flow fraction for surface 1
    Zn001:Roof001,          !- Surface name 2
    0.25;                  !- Flow fraction for surface 2
```

ZoneHVAC:HighTemperatureRadiant

The high temperature radiant system (gas-fired or electric) is a component of zone equipment that is intended to model any “high temperature” or “high intensity” radiant system where electric resistance or gas-fired combustion heating is used to supply energy (heat) to a building occupants directly as well as the building surfaces (wall, ceiling, or floor). The component is controlled by the radiant system controls defined in the syntax below and this control does not require the use of a zone thermostat unless the unit is being autosized. Note also that because this unit does not require a thermostat that in cases where no other systems are serving the zone in which this system resides that it will use the heating equipment priority to determine which system will run first. If the radiant system is serving a zone with forced air equipment, the radiant system will follow the priority order established by the zone thermostat but will still base its response on the controls defined by the user for the radiant system.

The control is accomplished by varying the electrical power supplied to or gas consumed by the unit. It is not intended to simulate low temperature electric or hydronic radiant systems. Those devices will be handled by a separate model and different input syntax (ref: the low temperature systems described elsewhere).

Field: Name

This field is an unique user assigned name for an instance of the high temperature radiant system. Any reference to this unit by another object will use this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the high temperature radiant system can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the high temperature radiant system is principally located and intended to affect.

Field: Maximum Power Input

This field is the maximum amount of energy (rate) that can be converted to heat in this particular radiant system in Watts. The controls for the radiant system will vary the amount of power supplied to the surface between zero input and the maximum power specified in this field as the lower and upper bounds, respectively. Note that if the user elects to autosize this field that a standard zone thermostat such as would be used for a forced air system must be defined as autosizing calculations are based on the zone thermostat value and not on the radiant system control values.

Field: Fuel Type

This field denotes the type of high temperature radiant heater: gas or electric. The user must specify this by inputting either the keyword "Gas" or "Electric" for this field.

Field: Combustion Efficiency

This field is the combustion efficiency for a gas high temperature radiant heater. This value should be greater than 0 and less than or equal to 1. It is intended to take into account any potential inefficiencies in the combustion process inside the radiant heater. The heater gas consumption is the ratio of heater output over the combustion efficiency. This parameter has no meaning for an electric high temperature radiant heater and is ignored when the previous field is equal to "Electric".

Field: Fraction of Input Converted to Radian Energy

This field specifies what fraction of the power input to the high temperature radiant heater is actually radiant heat transfer. The fraction should be between 0 and 1. In conjunction with the next two parameters, it defines the breakdown of how the power input to the heater is distributed to the rest of the zone. The sum of these fractions must be less than or equal to 1. If the fractions are less than one, the remaining energy is added to the zone as convective heat transfer. The radiant heat transfer from the heat is distributed to people and surfaces using the distribution fractions listed below.

Field: Fraction of Input Converted to Latent Energy

This field specifies the fraction of the power input to the high temperature radiant heater that is converted to a latent heat gain within the space. This may be appropriate when a combustion process produces moisture that is transferred into the space. The latent heat addition from a high temperature radiant heater is handled as any other latent heat gain within the space, affecting the moisture balance on the zone air.

Field: Fraction of Input that Is Lost

This field specifies the fraction of power input to the high temperature radiant heater that is "lost". This energy is a loss term, and this fraction of the input power has no effect on the zone heat balances.

Field: Temperature control type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the high temperature radiant system. The temperature denoted in the setpoint schedule can refer to one of three different temperatures: a mean air temperature, a mean radiant temperature, or an operative temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature
MeanRadiantTemperature
OperativeTemperature
MeanAirTemperatureSetpoint
MeanRadiantTemperatureSetpoint
OperativeTemperatureSetpoint

If the user does not select a control type, OperativeTemperature control is assumed by EnergyPlus. For the setpoint control strategies (those ending in Setpoint above), EnergyPlus will attempt to find the correct heater output to meet the heating setpoint temperature (see below) through iteration and interpolation. This will more closely match the operation of an actual thermostat, but it will require significantly longer execution times. For more information on the standard piecewise linear control algorithm used by the Mean Air Temperature, Mean Radiant Temperature, and Operative Temperature control types (the “non-Setpoint” controls), see the throttling range and control temperature schedule fields below for more information.

Field: Heating Throttling Range

This field specifies the range of temperature in degrees Celsius over which the radiant system throttles from zero heat input via the electric resistance wires up to the maximum defined by the maximum electrical power field described above. The throttling range parameter is used in conjunction with the control temperature (see below) to define the response of the system to various zone conditions. The heating control temperature schedule specifies the “setpoint” temperature where the power input to the system is at half of the maximum power input. For example, if the heating control temperature setpoint is currently 15°C and the heating throttling range is 2°C, the electrical power supplied to the radiant system will be zero when the controlling temperature (Mean Air Temperature, Mean Radiant Temperature, and Operative Temperature; see control type field above) is at or above 16°C and the maximum power input when the controlling temperature is at or below 14°C. This represents a throttling range of 2°C around the setpoint of 15°C. In between 14°C and 16°C, the power input to the radiant system is varied linearly.

Field: Heating Setpoint Temperature Schedule Name

This field specifies the heating setpoint or control temperature for the radiant system in degrees Celsius. Used in conjunction with the previous field (heating throttling range), it will define whether or not the system is running and the current power input to the radiant surface. Power input to the system is varied linearly around the setpoint temperature based on the throttling range and the maximum electrical power parameters (see above). It should be noted that this control schedule will allow different setpoint temperatures throughout the year for heating. In addition, this schedule may be different than the thermostatic control schedule defined for overall operation of components serving the zone in which the radiant system is located. The thermostatic control determines whether or not there is a heating or cooling load in the space and thus whether the systems should be operating. This field simply controls the flow rate to the radiant system.

Field: Fraction of Radiant Energy Incident on People

This field specifies the fraction of radiant heat transfer to the zone from the radiant heater that is incident directly on people within the space. This has an impact on the predicted thermal comfort of the zone occupants. Note that since the thermal comfort models only use the results of the zone heat balances this energy is accounted for within the heat balance as

convective energy, directly affecting the zone air heat balance. The basic assumption here is that most radiant energy falling on people will most likely be convected to the surroundings. This is a simplification of reality, but it maintains the overall energy balance.

Field Set: Surface Name, Fraction of radiant energy to Surface

The pairs of Surface Name, Fraction of Radiant Energy to Surface are used in several objects. There can be up to 20 specified.

Field: Surface <x> Name

This field is the name of the first surface to which radiant heat transfer from the high temperature radiant heater is distributed. Used in conjunction with the next field, it helps to define the distribution of the radiant energy on the surfaces within the zone. Note that up to 20 pairs of surface names and corresponding fractions may be entered for a single radiant heater system.

Field: Fraction of Radiant Energy to Surface <x>

This field is paired with the preceding surface name (previous field) to define the fraction of radiant heat transfer leaving the high temperature radiant system that is incident on a particular surface. Users should take into account the directionality of high temperature radiant heaters and their location when defining the value for this input field. Note that the sum of all fractions plus the fraction of radiant energy incident on people must add up to less than or equal to 1.

An example IDF with a high temperature radiant system is shown below.

ZoneHVAC:HighTemperatureRadiant Outputs

HVAC,Average, High Temperature Radiant Heating Rate[W]
HVAC,Sum, High Temperature Radiant Heating Energy[J]
HVAC,Average, High Temperature Radiant Gas Consumption Rate[W]
HVAC,Sum, High Temperature Radiant Gas Consumption[J]
HVAC,Average, High Temperature Radiant Electric Power[W]
HVAC,Sum, High Temperature Radiant Electric Consumption [J]

High Temperature Radiant Heating Rate[W]

This field reports the rate at which energy is transferred from the high temperature radiant system to the zone in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input. Note that this amount takes into account any combustion inefficiency and thus could be different than the gas consumption rate in a high temperature gas radiant system.

High Temperature Radiant Heating Energy[J]

This field reports the amount of energy transferred from the high temperature gas radiant system to the zone in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep. Note that this amount takes into account any combustion inefficiency and thus could be different than the gas consumption in a high temperature gas radiant system.

High Temperature Radiant Gas Consumption Rate[W]

This field reports the rate at which gas is “burned” in a high temperature gas radiant system in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input.

High Temperature Radiant Gas Consumption[J]

This field reports the amount of gas “burned” in a high temperature gas radiant system in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

High Temperature Radiant Electric Power[W]

This field reports the rate at which electric energy is “burned” in a high temperature electric radiant system in Watts. This rate is determined by the zone conditions and the control scheme defined in the user input.

High Temperature Radiant Electric Consumption[J]

This field reports the amount of electric energy “burned” in a high temperature electric radiant system in Joules. This amount is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

ZoneHVAC:VentilatedSlab

Ventilated slab systems in general use outdoor air to “precool” slabs with colder nighttime air. This method of precooling the thermal mass of a space can be very effective when nighttime temperatures are low and the mass of the system is high enough to provide a significant amount of cooling potential during the day to counteract internal heat gains within a zone. Nearly all ventilated slabs are simple systems such as that shown in the right side of Figure 115. The fan is shown in a blow through position, but the model will allow either a blow or draw through configuration.

Figure 115. Ventilated Slab model - basic system

Field: Name

This field is a unique user assigned name for an instance of a ventilated slab system. Any reference to this unit by another object will use this name. Other objects that use this ventilated slab system will reference it by this name.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the ventilated slab system can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit is not available and must be off for the hour.

Figure 116. Example operating schedule for Ventilated Slab

Field: Zone Name

This field is the name of the zone (Ref: Zone) in which the ventilated slab system is principally located and intended to affect. A system that is between two zones will still act upon each zone; however, the zone name referenced here should be the zone that controls the system response.

Field: Surface Name or Radiant Surface Group Name

This field is the name of the surface (Ref: Surface) or surface list (Ref: ZoneHVAC:VentilatedSlab:SlabGroup) in which the hollow cores are embedded/contained. This specification attaches the source or sinks from the radiant system to a particular surface

and the contribution of the system to the heat balances of that surface. If this field is a surface list, then the source or sink is attached to all of the surfaces in the list with the radiant system surface group defining the breakdown of how flow rate is split between the various surfaces. Only base surfaces (Walls, Roofs, Floors) are valid. Window/Door surfaces and Internal Mass are not valid surface types for embedded radiant systems.

Field: Maximum Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of air through the ventilated slab system in m^3/sec . This parameter should be some real number greater than zero.

Field: Outdoor Air Control Type

This field allows the user to control how outdoor air is used in the ventilated slab system. The ventilated slab system described by this syntax has its own outdoor air handler. The three options for outdoor air control are “**VariablePercent**”, “**FixedTemperature**” and “**FixedAmount**”. Those keywords are the only allowed choices for this parameter. In general, the variable percent control will attempt to vary the amount of outdoor air between some minimum and maximum schedules of fractions (see next two fields) to best meet the current heating or cooling load. The fixed temperature control will vary the amount of outdoor air between the minimum schedule (fraction of maximum, see next field) and 100% available outdoor air to come as close as possible to a desired mixed air temperature (see two fields down) that can be scheduled. The fixed amount control will fix the outdoor air flow rate as minimum outdoor air flow rate and schedule specified by the user and automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate. More information on the controls and operation of the ventilated slab are given in the section above (preceding the IDF description).

Field: Minimum Outdoor Air Flow Rate

This field allows the user to enter the minimum volumetric flow rate of outdoor air (in m^3/sec) that will be brought in to the ventilated slab. The actual minimum outdoor air flow rate will be this number multiplied by the schedule value from the minimum outdoor air schedule. If “**FixedAmount**” type is selected as the outdoor air control strategy, the outdoor air flow rate will be fixed at the value of this field and the ventilated slab will automatically set the maximum and minimum outside flow rate to be equal by ignoring the maximum outdoor air flow rate.

Field: Minimum Outdoor Air Schedule Name

This field contains a schedule name (ref: Schedule) that should contain values for the minimum outdoor air used by the ventilated slab system for IAQ or other reasons. Note that if the ventilated slab is scheduled off or if there is no load sensed in the zone that the system will not operate even to achieve the minimum air fraction. However, if the system is operating, it will always bring in at least this fraction of the minimum air flow rate (see minimum air flow rate field above). If “**FixedAmount**” type is selected as the outdoor air control strategy, the actual outdoor air flow rate will be this number multiplied by the minimum outdoor air flow rate in the field above. The ventilated slab will automatically set the maximum and minimum outdoor air schedule to be equal by ignoring the maximum outdoor air schedule.

Field: Maximum Outdoor Air Flow Rate

This field allows the user to enter the maximum volumetric flow rate of outdoor air that can be brought into the ventilated slab in m^3/sec . This parameter should be some real number greater than zero. Note that the value for this parameter may be less than the maximum air flow rate of the ventilated slab and this may affect the maximum fraction of outdoor air within the control strategy defined above. This parameter is an absolute maximum and will supercede any scheduled fraction of the ventilated slab maximum airflow rate. If

“FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air flow rate specified in the field above.

Field: Maximum Outdoor Air Fraction or Temperature Schedule Name

This field can have one of two meanings depending the type of control selected in the outdoor air control type parameter above. If “VariablePercent” or “FixedAmount” was selected, then this field is a schedule name (ref: Schedule) corresponding to a maximum air fraction schedule. Furthermore, if “FixedAmount” type is selected as the outdoor air control strategy, this field will be ignored and be automatically set to be equal to the minimum outdoor air fraction specified in the field below. Note that this is a fraction of the maximum airflow rate field (see parameter above) for the ventilated slab. If “FixedTemperature” control was selected, then this field is still a schedule name (ref: Schedule), but it corresponds to a schedule of mixed air temperatures that the outdoor air control will try to attain.

Field: System Configuration Type

This field allows the user to control how the air is circulated using the ventilated slab system. The options for system configuration are

SlabOnly
SlabAndZone
SeriesSlabs

In the **SlabOnly**, the ventilation air is sent to the slab only and does not enter the zone. In the **SlabAndZone**, the air first enters the slab and then is delivered to the zone before returning to the system. With the **SeriesSlabs** option, the user specifies a list of slabs (ZoneHVAC:VentilatedSlab:SlabGroup). This list determines the order of slabs through which the air passes. In this option, air is not delivered to any zone.

Field: Hollow Core Inside Diameter

This field is the inside diameter of the cores through which air is circulated for the system being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the circulated air to the inside surface of the ventilated slab.

Field: Hollow Core Length

This field is the length of core embedded in the surface named above in the surface name field. In other words, this should be the distance that air travels as it through the slab. The length of the hollow core in the slab should be entered in meters and is used to determine the effectiveness of heat transfer from the air being circulated through the cores and the core inside surface. Longer core lengths result in more heat transferred to/from the radiant surface to the circulating fluid.

Field: Number of Cores

This field allows the user to specify how many cores there are in the ventilated slab. Air flow will be divided equally among the different cores.

Field: Temperature Control Type

This field specifies along with the throttling range and setpoint schedules how the user wishes to control the ventilated slab system. The temperature denoted in the set temperature schedule can refer to one of seven different temperatures: the zone mean air temperature, the zone mean radiant temperature, the zone operative temperature, the surface temperature of the ventilated slab, the outdoor dry-bulb temperature, the outdoor wet-bulb temperature, or the dewpoint temperature of zone mean air temperature. The choice of temperature is controlled by the current field—temperature control type. The user must select from the following options:

MeanAirTemperature

MeanRadiantTemperature
OperativeTemperature
OutdoorDryBulbTemperature
OutdoorWetBulbTemperature
SurfaceTemperature
ZoneAirDewPointTemperature

If the user does not select a control type, **MeanAirTemperature** control is assumed by EnergyPlus. See the control temperature schedule fields below for more information.

Field: Heating High Air Temperature Schedule Name

This field specifies the high air temperature in degrees Celsius for the temperature control of a ventilated slab system. Air and control temperatures for heating work together to provide a linear function that determines the air temperature sent to the ventilated slab. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet air temperature is set to the low air temperature. If the control temperature is below the low temperature, then the inlet air temperature is set to the high air temperature. If the control temperature is between the high and low value, then the inlet air temperature is linearly interpolated between the low and high air temperature values.

Field: Heating Low Air Temperature Schedule Name

This field specifies the low air temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

Field: Heating High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

Field: Heating Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a ventilated slab. For more information on its interpretation, see Heating High Air Temperature Schedule above.

Field: Cooling High Air Temperature Schedule Name

This field specifies the high air temperature in degrees Celsius for the temperature control of a ventilated slab system. Air and control temperatures for cooling work together to provide a linear function that determines the air temperature sent to the ventilated slab system. The current control temperature (see Temperature Control Type above) is compared to the high and low control temperatures at the current time. If the control temperature is above the high temperature, then the inlet air temperature is set to the low air temperature. If the control temperature is below the low temperature, then the inlet air temperature is set to the high air temperature. If the control temperature is between the high and low value, then the inlet air temperature is linearly interpolated between the low and high air temperature values.

Field: Cooling Low Air Temperature Schedule Name

This field specifies the low air temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

Field: Cooling High Control Temperature Schedule Name

This field specifies the high control temperature in degrees Celsius for the temperature control of a constant flow cooling radiant system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

Field: Cooling Low Control Temperature Schedule Name

This field specifies the low control temperature in degrees Celsius for the temperature control of a ventilated slab system. For more information on its interpretation, see Cooling High Air Temperature Schedule above.

Field: Return Air Node Name

This field is a node name used to identify the node that serves as the zone return air inlet to the ventilated slab system. This node is one of the inlets to the outdoor air mixer which is implicit in the ventilated slab system model. For “SlabAndZone” configuration, the Return Air Node will typically be the same node as a zone exhaust node. For “SlabOnly” or “SeriesSlabs” configuration, this node name is required but will have zero flow.

Field: Slab In Node Name

This field is a node name used to identify the node that serves as the inlet of the ventilated slab or series of slabs, after the outdoor air mixer, fan, and optional coils.

Field: Zone Supply Air Node Name

This field is a node name used to identify the node that serves as the outlet from the ventilated slab system to the zone when using the “SlabAndZone” configuration. It is the node exiting the slab section of the system. This node will typically be the same node as a zone inlet node. In the case of “SlabOnly” or “SeriesSlabs” configuration, this field will be ignored and it should be left BLANK.

Field: Outdoor Air Node Name

This field is a node name used to identify the node associated with fresh outdoor air brought into the ventilated slab system outdoor air mixer. This node should also be specified in an OutdoorAir:Node or OutdoorAir:NodeList object.

Field: Relief Air Node Name

This field is a node name used to identify the node associated with air exhausted out of the ventilated slab system to the outdoor environment.

Field: Outdoor Air Mixer Outlet Node Name

This field is a node name used to identify the node associated with the “mixed” air of the ventilated slab. These conditions are post-“mixing box” since they are the conditions of the fraction of return air combined with the outdoor air. Since this is a simple system, this can also be viewed as the conditions of the air being sent to the coils.

Field: Fan Outlet Node Name

This field is a node name used to identify the node that serves as the air outlet from the fan.

Field: Fan Name

This field is the name of a fan (ref: Fan:ConstantVolume) that is part of the ventilated slab system. This name links the ventilated slab to particular fan data entered elsewhere in the input data file. A fan name is required since it is the prime mover of air in the ventilated slab system.

Field: Coil Option Type

This field allows the user to specify the coil operating options as one of the following options:

None
Heating
Cooling
HeatingAndCooling

If **None** is selected, the ventilated slab does not have any coils, and any other input will be ignored. If either **Heating** or **Cooling** is selected, only a heating or cooling coil, respectively, is present. Thus, only four more inputs will be expected. If **HeatingAndCooling** is selected, both heating and cooling coil input must be entered, and the ventilated slab will have both a heating and a cooling coil.

Field: Heating Coil Object Type

This field is the type of coil (ref: Coil:Heating:Water, Coil:Heating:Electric, Coil:Heating:Gas, Coil:Heating:Steam) that is used for heating in the ventilated slab system. This field must be one of the following keywords: Coil:Heating:Water, Coil:Heating:Electric, Coil:Heating:Gas, Coil:Heating:Steam. It is used in conjunction with the heating coil name (see next field) to specify the heating coil present within the system.

Field: Heating Coil Name

This field is the name of the heating coil that is part of the ventilated slab system. It is assumed that there is always some sort of heating coil associated with a ventilated slab system. This name links the ventilated slab to particular heating coil data entered elsewhere in the input data file.

Field: Hot Water or Steam Inlet Node Name

This field corresponds to the water inlet node to the heating coil for a water coil. The water inlet node controls how a water heating coil operates. This field is ignored/not needed for gas and electric heating coils.

Field: Cooling Coil Object Type

This field is the name of the cooling coil (ref: Coil:Cooling:Water, Coil:Cooling:Water:DetailedGeometry, CoilSystem:Cooling:Water:HeatExchangerAssisted) that is part of the ventilated slab system. This name links the ventilated slab system to particular cooling coil data entered elsewhere in the input data file. If no cooling coil is present, the previous field may be followed by a semi-colon and the remaining parameters in this statement may be ignored.

Field: Cooling Coil Name

This field is the name of the cooling coil that is part of the ventilated slab system. It is assumed that there is always some sort of cooling coil associated with a ventilated slab system. This name links the ventilated slab to particular cooling coil data entered elsewhere in the input data file.

Field: Cold Water Inlet Node Name

This field corresponds to the water inlet node to the cooling coil. The water inlet node controls how a water cooling coil operates and is required for the ventilated slab system that has a cooling coil associated with it to function properly.

Field: Availability Manager List Name

This optional input field is the name of an AvailabilityManagerAssignmentList object. An Availability Manager Assignment List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this ventilated slab object's fan. If the ventilated slab is available (per the Availability Schedule Name input field above) and this input field has a valid availability manager assignment list name, then the availability managers in the list determine when and if the fan of this ventilated slab object should be on or off.

An example IDF with a ventilated slab is shown below.

Ventilated Slab Radiant Heating Rate [W]

This field reports the radiant heating input rate of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilated slab system.

Ventilated Slab Radiant Heating Energy [J]

This field is the heating radiant input of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilated slab system, and the timestep.

Ventilated Slab Radiant Cooling Rate [W]

This field reports the radiant cooling input rate to the ventilated slab system in Watts. This is the heat sink to the surface that is defined as the ventilated slab system. The cooling rate is determined by the zone conditions and the control scheme defined in the user input.

Ventilated Slab Radiant Cooling Energy [J]

This field reports the radiant cooling input to the ventilated slab system in Joules. This is the heat sink to the surface that is defined as the radiant system. The cooling rate is determined by the zone conditions, the control scheme defined in the user input, and the timestep.

Ventilated Slab Coil Heating Rate [W]

This field reports the heating input rate of the heating coil of ventilated slab system the zone it is serving in Watts. This is determined by return air and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Coil Heating Energy [J]

This field is the heating output of the heating coil of the ventilated slab system the zone it is serving in Joules over the timestep being reported. This is determined by return air and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Total Coil Cooling Rate [W]

This field reports the total cooling (sensible plus latent) output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Total Coil Cooling Energy [J]

This field is the total cooling (sensible plus latent) output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Sensible Coil Cooling Rate [W]

This field reports the sensible cooling output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Sensible Coil Cooling Energy [J]

This field is the sensible cooling output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Latent Coil Cooling Rate [W]

This field reports the latent cooling output rate of the cooling coil of the ventilated slab system to the zone it is serving in Watts. This is determined by outlet and zone air conditions and the mass flow rate through the ventilation slab system.

Ventilated Slab Latent Coil Cooling Energy [J]

This field is the latent cooling output of the cooling coil of the ventilated slab system to the zone it is serving in Joules over the timestep being reported. This is determined by outlet and zone air conditions, the mass flow rate through the ventilation slab system, and the timestep.

Ventilated Slab Air Mass Flow Rate [kg/s]

This field reports the mass flow rate of air through the ventilated slab system in kilograms per second.

Ventilated Slab Fan Electric Power [W]

This field reports the electric power consumption rate of the fan of the ventilated slab system in Watts.

Ventilated Slab Fan Electric Consumption [J]

This field reports the electric power consumed by the fan of the ventilated slab system over the timestep in Joules.

Ventilated Slab Slab Inlet Air Temperature [C]

This field reports the temperature of air entering the ventilated slab system in Celsius.

Ventilated Slab Slab Outlet Air Temperature [C]

This field reports the temperature of air leaving the ventilated slab system in Celsius.

Ventilated Slab Zone Inlet Air Temperature [C]

This field reports the temperature of air entering the zone in Celsius.

Ventilated Slab Return Air Temperature [C]

This field reports the temperature of air leaving the zone in Celsius. When system does not circulate air to zone("SlabOnly" Configuration), the slab outlet temperature and return air temperature will be the same.

Ventilated Slab Fan Outlet Air Temperature [C]

This field reports the fan outlet air temperature for the ventilated slab system in Celsius.

Ventilated Slab Fan Availability Status []

This is the availability status of the ventilated slab fan. This status flag is a result of the calculations made by the Availability Manager(s) listed in an AvailabilityManagerAssignmentList object and/or calculations made by Hybrid Ventilation Manager object. The AvailabilityManagerAssignmentList is an optional input in the ventilated slab object. When a single availability manager is used in an Availability Manager Assignment List, this is also the availability status reported by the specific availability manager (Ref. AvailabilityManager:`* Outputs`). For multiple availability managers in an Availability Manager Assignment List along with Hybrid Ventilation Manager, rules to determine fan availability status are described in the section 'Group – System Availability Managers'. The control status outputs are represented using integers 0 through 3. These integers represent NoAction (0), ForceOff (1), CycleOn (2), and CycleOnZoneFansOnly (3). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the

“detailed” reporting frequency (Ref. Output:Variable) to view the availability status at each simulation timestep.

ZoneHVAC:VentilatedSlab:SlabGroup

A ventilated slab system may consist of multiple active slabs that are serving to condition the zone. Slabs that act serially can be specified as multiple radiant systems using the standard ventilated slab input described above. This list of surfaces (the name it is assigned) replaces the name of a single surface in the ventilated slab system input described above.

Field : Name of Ventilated Slab Surface Group

This field is a unique user assigned name for the list of surfaces that are acting in coordination with one another. Any reference to this list by a ventilated slab system will use this name.

Field: Zone Name

This field is the name of the zone in which the surface is principally located and intended to affect.

Field: Surface Name

This field is the name of a surface in the zone being conditioned by the ventilated slab system. Only base surfaces like walls, floors and roofs are valid. Door/Window Surface and Internal Mass are not valid surface types for the ventilated slab system.

Field: Core Diameter

This field is the inside diameter of the cores through which air is circulated for the surface being defined by this statement. The inside diameter should be recorded in meters and is used to determine the convective heat transfer from the circulated air to the inside surface of the ventilated slab.

Field: Core length

This field is the length of core embedded in the surface named above in the surface name field. In other words, this should be the distance that air travels as it through the slab. The length of the hollow core in the surface should be entered in meters and is used to determine the effectiveness of heat transfer from the air being circulated through the cores and the core inside surface. Longer core lengths result in more heat transferred to/from the radiant surface to the circulating fluid.

Field: Number of Cores

This field allows the user to specify how many cores there are in the ventilated slab. Air flow will be divided equally among the different cores.

Field: Slab Inlet Node Name

This field is a node name (character string) used to identify the node that serves as the inlet (air side) to the surface. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

Field: Slab Outlet Node Name

This field is a node name (character string) used to identify the node that serves as the outlet (air side) of the surface. In EnergyPlus, nodes represent points between components or at various points in the loops. While a node name may be referenced more than once in an input data file, each node must have a unique name.

An Example IDF with a ventilated slab system is shown below

```

Group – Refrigeration

There are two ways to model a supermarket refrigeration system. The first, and simplest, approach models the combination of compressor(s) and condenser as a single refrigeration compressor rack object. (A list is used to enter multiple case or walk-in names.)

For the first approach, the input objects needed are:

- One **Refrigeration:CompressorRack** object
- At least one refrigeration load, which may be any combination of:
 - **Refrigeration:Case** or
 - **Refrigeration:WalkIn** or
 - **Refrigeration:CaseAndWalkInList** objects .

The second approach requires more input objects but also allows the user to model more complex systems. This detailed approach must be used whenever loads are transferred from one system to another, such as with secondary loops, cascade condensers, or mechanical subcoolers. Again lists are used to enter multiple load or compressor names.

For the detailed approach, the input objects needed are:

- One **Refrigeration:System** object
- At least one refrigeration load object which may include any combination of:
 - **Refrigeration:Case**,
 - **Refrigeration:WalkIn**,
 - **Refrigeration:CaseAndWalkInList** (may include any combination of cases and walk in cooler names, OR, a list of air chiller names)
 - **Refrigeration:SecondarySystem**,
 - **Refrigeration:Condenser:Cascade** (as a load, cooling a lower-temperature system) objects,
 - **Refrigeration:TransferLoadList** (may include cascade condenser loads and/or secondary loop loads)
 - **Refrigeration:AirChiller**
- At least one **Refrigeration:Compressor** object (multiple compressors are entered using a **Refrigeration:CompressorList**),
- One condenser object which may be either:

- Refrigeration:Condenser:AirCooled,
- Refrigeration:Condenser:EvaporativeCooled,
- Refrigeration:Condenser:WaterCooled, or
- Refrigeration:Condenser:Cascade (rejecting heat from this system)
- The object Refrigeration:Subcooler may optionally be included to describe either a liquid suction or mechanical subcooler.

Output variables are also available to describe the total heat exchange between all refrigeration objects and the zones containing these objects. These variables are described at the end of this section after all the refrigeration objects.

Refrigeration:CompressorRack

The refrigeration compressor rack object works in conjunction with the refrigeration case and walkin objects (Ref. Refrigeration:Case and Refrigeration:WalkIn) to simulate the performance of a refrigerated case system. This object models the electric consumption of the rack compressors and the condenser fans. Heat removed from the refrigerated cases, walkins, and compressor/condenser fan heat can be rejected either outdoors or to a zone. Compressor rack waste heat can also be reclaimed for use by an optional air- or water-heating coil (Ref. Coil:Heating:Desuperheater and Coil:WaterHeating:Desuperheater).

If heat is rejected outdoors, condenser cooling can either be accomplished by direct air flow, evaporative water cooling, or a by water-cooled condenser with appropriate plant loop piping. With evaporative cooling, water is sprayed through the air stream to effectively lower the air temperature experienced by the condenser coil as a result of water evaporation. The use of a water-cooled condenser requires the definition of a plant loop to supply cooling to the condenser. Waste heat can be reclaimed and stored using a water storage device.

The inputs for the compressor rack object include a name, the heat rejection location, the compressor rack coefficient of performance (COP) at design conditions, the design condenser fan power, and the type of condenser cooling. The model requires two curve objects to describe performance at off-design conditions. If the condenser is water-cooled, the inlet and outlet node names as well as the water outlet temperature schedule name are required. If the condenser has evaporative cooling, additional inputs for evaporative condenser effectiveness, condenser air flow rate, basin heater parameters, water pump power, water source, and an evaporative cooling availability schedule are available. The names of refrigerated cases and walkins connected to the compressor rack are the final inputs to the model.

Field: Name

A unique user-assigned name for an instance of a refrigeration compressor rack. Any reference to this compressor rack by another object will use this name.

Field: Heat Rejection Location

The location of the compressor rack's condenser. The compressor rack condenser heat can be directed "Outdoors" to model an outdoor air or water-cooled condenser or "Zone" to model a condenser located in a zone (e.g., a stand-alone packaged refrigerated case with integral condenser located in a conditioned zone). The default for this field is "Outdoors". If the heat rejection location is "Zone" and no walk-in coolers are served by this compressor rack, then all refrigerated cases connected to this compressor rack must be located in the same zone. If however, walk-in coolers are also served by this compressor rack, then the heat rejection zone name must be specified (see Heat Rejection Zone Name field below) and cases and walk-ins can be located in multiple zones.

NOTE: When modeling a heat reclaim coil, the heat rejection location must be "Outdoors". If the heat rejection location is "Zone", the total amount of waste heat available for reclaim (e.g., by a desuperheater heating coil) is set to zero by this compressor rack object and the simulation proceeds.

Field: Design Compressor Rack COP

The coefficient of performance (COP) for the compressor rack at design conditions (compressors only, excluding condenser fan power). This value must be greater than zero, with a default value of 2.0 if this field is left blank. This value should represent the compressor rack COP corresponding to the lowest evaporating temperature of any case or walkin served by the rack.

Field: Compressor Rack COP Function of Temperature Curve Name

The name of the curve object defining the change in compressor rack COP as a function of the temperature of air entering the condenser. The curve object will be evaluated using the zone air dry-bulb temperature when rack heat rejection location equals "Zone" and the outdoor air dry-bulb temperature when rack heat rejection location equals "Outdoors" and the condenser type is air-cooled. As explained below, if the condenser is cooled by evaporative or water loop cooling, the curve object is evaluated using an effective temperature. The output from this curve is multiplied by the design compressor rack COP to yield the actual COP at the specific air temperature entering the condenser. This curve must be cubic or quadratic (Curve:Cubic or Curve:Quadratic), and should be normalized to 1.0 at the condenser entering air temperature at which the design compressor rack COP occurs. This curve should represent the compressor rack COP corresponding to the lowest evaporating temperature of any case served by the rack.

Field: Design Condenser Fan Power

This field defines the design power for the condenser fan(s) in Watts. This field is applicable for air or evaporative cooling only. If the condenser is water-cooled, the fan power is captured in the cooling object (e.g., cooling tower). If applicable, this value must be greater than 0.0, with a default value of 250 Watts if this field is left blank.

Field: Condenser Fan Power Function of Temperature Curve Name

This field is the name of the curve object defining the change in condenser fan power as a function of the temperature of air entering the condenser. This curve is used to simulate the modulation of air flow by the condenser fans (e.g., staging, multi-speed, or variable speed) as a function of temperature. The curve object will be evaluated using the zone air dry-bulb temperature when rack heat rejection location equals "Zone" and the outdoor air dry-bulb temperature when rack heat rejection location equals "Outdoors" and the condenser type is air-cooled. As explained below, if the condenser is cooled by evaporative cooling, the curve object is evaluated using an effective temperature. The output from this curve is multiplied by the design condenser fan power to yield the actual fan power at the specific air temperature entering the condenser. This curve must be cubic or quadratic (Curve:Cubic or Curve:Quadratic), and should be normalized to 1.0 at the condenser entering air temperature at which the design condenser fan power occurs. The actual condenser fan power is not allowed to exceed the design condenser fan power defined in the previous input field or go below zero (i.e., the output of the curve object is limited to values from 0.0 to 1.0). If this field is left blank, then the model assumes the condenser fan power is at the design power level when any of the refrigerated cases connected to this rack are operating.

Field: Condenser Type

When the heat rejection location is "Outdoors", the condenser may be either cooled by dry air by specifying "AirCooled", by wet evaporative cooling by specifying "EvaporativelyCooled", or by a water loop by specifying "WaterCooled". If the condenser type is "WaterCooled", then a

plant cooling loop will need to be defined using other EnergyPlus objects, e.g., plant loop, pump, cooling tower, etc. The default value is “AirCooled”.

Field: Water-cooled Condenser Inlet Node Name

When the condenser type is “WaterCooled”, a node name for the water-side condenser inlet must be provided.

Field: Water-cooled Condenser Outlet Node Name

When the condenser type is “WaterCooled”, a node name for the water-side condenser outlet must be provided.

Field: Water-cooled Loop Flow Type

When the condenser type is “WaterCooled”, the type of flow loop should be specified. The two choices are **VariableFlow**, in which a Pump:VariableSpeed needs to be included in the plant loop, or **ConstantFlow**, in which the loop circuit has a constant flow rate, typically associated with a Pump:ConstantSpeed object. If the flow type is VariableFlow, the flow needed to remove the condenser heat energy will be calculated and requested of the pump. If the flow type is Constant Flow, the outlet water temperature will be determined based on the fixed loop flow rate and heat energy to be removed. The default type is **VariableFlow**. Refer to additional discussion in the Engineering Reference.

Field: Water-cooled Condenser Outlet Temperature Schedule Name

When the condenser type is “WaterCooled”, and when the water-cooled loop flow type is “Variable Flow”, the name of a schedule (Ref: Schedule) that defines the desired condenser water outlet temperature must be provided. The schedule may define an outlet temperature that varies through time.

Field: Water-cooled Condenser Design Flow Rate

When the condenser type is “WaterCooled”, and when the water-cooled loop flow type is “Constant Flow”, this is the design water flow rate in m³/s that will be requested initially. This requested flow will be passed to the loop simulation, and resulting actual flow will be dependent upon supply system capabilities (e.g., pump capability). The design flow rate must always be less than the maximum flow rate, defined below.

Field: Water-cooled Condenser Maximum Flow Rate

When the condenser type is “Water Cooled”, this is the maximum water flow rate in m³/s that will be allowed through the condenser. When the loop flow type is Variable Flow, if the calculated flow rate is higher than the maximum flow rate, an error message will be generated, and the flow rate will be reset to the maximum flow rate.

Field: Water-cooled Condenser Maximum Water Outlet Temperature

When the condenser type is “WaterCooled”, this field specifies the maximum allowed water temperature in degrees C leaving the compressor rack condenser. The default value is 55 degrees C.

Field: Water-cooled Condenser Minimum Water Inlet Temperature

When the condenser type is “WaterCooled”, this field specifies the minimum allowed water temperature in degrees C entering the compressor rack condenser. The default value is 10 degrees C. Refer to additional discussion in the Engineering Reference.

Field: Evaporative Condenser Availability Schedule Name

When the condenser type is “EvaporativelyCooled”, the name of the optional schedule (Ref: Schedule) that specifies the time periods that evaporative cooling is available/unavailable. In some colder climates, evaporative cooling is periodically discontinued and the basin sumps drained to avoid freezing. In these times, the condenser runs as a typical dry air cooled

condenser, and related evaporative cooling systems (e.g., water pump, basin heaters) do not operate. Use of this optional schedule permits modeling of planned, seasonal interruptions of evaporative cooling. All schedule values must be greater than or equal to zero. Typically, an ON/OFF schedule type is used with values being either 0 or 1. A schedule value of 1 indicates that evaporative cooling is available during the defined time period, and a value of 0 denotes that evaporative cooling is not available during the defined time period. If the schedule name is omitted (blank) and Condenser Type = “Evap Cooled”, then the model assumes that evaporative cooling of the condenser is available for the entire simulation period.

Field: Evaporative Condenser Effectiveness

When the condenser type is “EvaporativelyCooled”, this field specifies the effectiveness of the evaporative system in modifying the temperature of the air entering the condenser coil. The resulting effective temperature is determined as

$$T_{\text{effective}} = T_{\text{owb}} + (1 - \varepsilon) * [T_{\text{odb}} - T_{\text{owb}}]$$

where:

$T_{\text{effective}}$	= effective dry-bulb temperature of air entering the condenser cooling coil (°C)
T_{owb}	= outdoor air wet-bulb temperature (°C)
T_{odb}	= outdoor air dry-bulb temperature (°C)
ε	= evaporative condenser effectiveness.

The resulting condenser inlet air temperature is used by the Compressor Rack COP as a Function of Temperature Curve and the Condenser Fan Power as a Function of Temperature Curve. The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0.

If the two function-of-temperature curves (i.e., Compressor Rack COP as a Function of Temperature Curve and Condenser Fan Power as a Function of Temperature Curve) are based on wet-bulb temperature rather than dry-bulb temperature, the evaporative condenser effectiveness should be set to 1.0 for consistency.

Field: Evaporative Condenser Air Flow Rate

When the condenser type is “EvaporativelyCooled”, the air volume flow rate, in m^3 per second, entering the evaporative condenser. This value is used to calculate the amount of water evaporated when evaporatively cooling the condenser inlet air. The value for this field must be greater than zero. This input field is also autocalculatable, equivalent to 0.000144 m^3/s per watt of total cooling capacity [850 cfm/ton] where the total cooling capacity is the sum of the rated total cooling capacities for the refrigerated cases connected to this compressor rack (Ref. Refrigeration:Case).

Field: Basin Heater Capacity

When the condenser type is “EvaporativelyCooled”, this field defines the power level of the basin heater, if applicable, used to avoid water freezing in an outdoor evaporative cooler basin. This numeric field contains the capacity of the electric basin heater in Watts per degree Kelvin. This field is used in conjunction with the Basin Heater Set Point Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the dry-bulb temperature of the condenser coil inlet air. The basin heater only operates when the condenser fan is off (i.e., no compressor heat rejection). The basin heater capacity must be greater than or equal to zero, with a default value of 200 W/K if this field is left blank.

Field: Basin Heater Setpoint Temperature

When the condenser type is “EvaporativelyCooled”, this numeric field contains the set point temperature (°C) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this set point temperature, as long as the condenser fan is off. The default value is 2°C if this field is left blank.

Field: Design Evaporative Condenser Water Pump Power

When the condenser type is “EvaporativelyCooled”, the rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The value for this field must be greater than or equal to 0, with a default value of 1000 Watts if this field is left blank. This input field is also autocalculatable, equivalent to 0.004266 W per watt [15 W/ton] of total cooling capacity where the total cooling capacity is the sum of the rated total cooling capacities for the refrigerated cases and walk-ins connected to this compressor rack (Ref. Refrigeration:Case and Refrigeration:WalkIn)).

Field: Evaporative Water Supply Tank Name

When the condenser type is “EvaporativelyCooled”, this field is used to define where the compressor rack obtains water used for evaporative cooling of its condenser. If this field is left blank, the unit will obtain water directly from the mains (Ref. Water Mains Temperatures). If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank.

Field: Condenser Air Inlet Node Name

This optional alpha field contains the name of the node from which the outdoor compressor rack condenser draws its outdoor air. This field is applicable only when the heat rejection location is “Outdoors” (if the heat rejection location is “Zone”, this field is disregarded). If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, this node name must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Refrigeration Case Name or WalkIn Name or CaseAndWalkInList Name

This alpha field is the name of a single refrigerated case, a single walk in cooler, the name of a CaseAndWalkInList for multiple refrigerated cases and/or walk-ins, the name of a refrigeration chiller, or the name of a CaseAndWalkInList for multiple refrigeration chillers connected to this compressor rack. Note that if a CaseAndWalkInList contains the name(s) of refrigeration chillers, it CANNOT have the name(s) or any refrigerated cases or walkins . This field is required.

Field: Heat Rejection Zone Name

If the Heat Rejection Location is “Zone” and any walk-in coolers are connected to this compressor rack, then this field is required. The compressor rack heat rejection will impact the air heat balance in this zone.

The following is an example input for a Refrigeration Compressor Rack with water cooled condenser.

Compressor Rack Condenser Mass Flow Rate [kg/s]

When condenser type is Water Cooled, this is the mass flow rate of water flowing through the water cooled condenser.

Compressor Rack Condenser Heat Transfer Rate [W]

When condenser type is Water Cooled, this is the total heat transfer across the condenser (i.e., compressor energy and case cooling).

Compressor Rack Condenser Heat Transfer Energy [J]

When condenser type is Water Cooled, this is the total heat energy flowing across the condenser for the timestep being reported.

IF THE RACK SERVES CASES AND OR WALKINS:

Refrigeration Compressor Rack Electric Power [W]

This output is the electric power input to the rack compressor(s) in Watts.

Refrigeration Compressor Rack Electric Consumption [J]

This is the electricity consumption of the rack compressor(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Rack Condenser Fan Electric Power [W]

This output is the electric input to the rack condenser fan(s) in Watts.

Refrigeration Compressor Rack Condenser Fan Electric Consumption [J]

This is the electricity consumption of the rack condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Rack Total Heat Transfer Rate [W]

This output is the total heat transfer rate of the refrigeration compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected to this rack. This value does not include compressor or condenser fan heat.

Refrigeration Compressor Rack Total Heat Transfer Energy [J]

This is the total heat transfer of the refrigeration compressor rack in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Rack COP [W/W]

This field is the refrigeration compressor rack coefficient of performance. It is the actual compressor rack COP for the timestep being reported, accounting for the COP variation as a function of temperature. It is calculated as the Design Compressor Rack COP times the Compressor Rack COP as a Function of Temperature Curve evaluated at the effective condenser entering air temperature for the timestep being reported.

Refrigeration Compressor Rack Evap Condenser Pump Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the compressor rack condenser.

Refrigeration Compressor Rack Evap Condenser Pump Elec Consumption [J]

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration Compressor Rack Evap Cond Basin Heater Elec Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the compressor rack condenser.

Refrigeration Compressor Rack Evap Cond Basin Heater Elec Consumption [J]

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter).

Refrigeration Compressor Rack Evap Condenser Water Consumption Rate [m^3/s]

The volumetric flow rate in m^3/s of water consumed while providing evaporative cooling of the compressor rack condenser.

Refrigeration Compressor Rack Evap Condenser Water Consumption [m^3]

This is the water consumed by evaporation in m^3 while providing evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a

report meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration Compressor Rack Sensible Heating Rate To Zone [W]

This field is the rate of sensible heating in Watts provided to the zone by condenser waste heat rejection, which impacts the zone air heat balance.

Refrigeration Compressor Rack Sensible Heating Energy To Zone [J]

This field is the sensible heating energy in Joules provided to the zone by condenser waste heat rejection for the timestep being reported.

Refrigeration Compressor Rack Sensible Heating Rate To HVAC Return Air [W]

This field is the rate of sensible heating in Watts provided by condenser waste heat rejection to the HVAC return air (zone return air path outlet node), which impacts the HVAC return air temperature. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigeration Compressor Rack Sensible Heating Energy To HVAC Return Air [J]

This field is the sensible heating energy in Joules provided by condenser waste heat rejection to the HVAC return air (zone return air path outlet node) for the timestep being reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

IF THE RACK SERVES CHILLERS

Refrigeration Chiller Compressor Rack Electric Power [W]

This output is the electric power input to the rack compressor(s) in Watts.

Refrigeration Chiller Compressor Rack Electric Consumption [J]

This is the electricity consumption of the rack compressor(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller Compressor Rack Condenser Fan Electric Power [W]

This output is the electric input to the rack condenser fan(s) in Watts.

Refrigeration Chiller Compressor Rack Condenser Fan Electric Consumption [J]

This is the electricity consumption of the rack condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller Compressor Rack Total Heat Transfer Rate [W]

This output is the total heat transfer rate of the refrigeration compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected to this rack. This value does not include compressor or condenser fan heat.

Refrigeration Chiller Compressor Rack Total Heat Transfer Energy [J]

This is the total heat transfer of the refrigeration compressor rack in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller Compressor Rack COP [W/W]

This field is the refrigeration compressor rack coefficient of performance. It is the actual compressor rack COP for the timestep being reported, accounting for the COP variation as a function of temperature. It is calculated as the Design Compressor Rack COP times the Compressor Rack COP as a Function of Temperature Curve evaluated at the effective condenser entering air temperature for the timestep being reported.

Refrigeration Chiller Compressor Rack Evap Condenser Pump Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the compressor rack condenser.

Refrigeration Chiller Compressor Rack Evap Condenser Pump Elec Consumption [J]

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration Chiller Compressor Rack Evap Cond Basin Heater Elec Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the compressor rack condenser.

Refrigeration Chiller Compressor Rack Evap Cond Basin Heater Elec Consumption [J]

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Output:Meter).

Refrigeration Chiller Compressor Rack Evap Condenser Water Consumption Rate [m^3/s]

The volumetric flow rate in m^3/s of water consumed while providing evaporative cooling of the compressor rack condenser.

Refrigeration Chiller Compressor Rack Evap Condenser Water Consumption [m^3]

This is the water consumed by evaporation in m^3 while providing evaporative cooling of the compressor rack condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration Chiller Compressor Rack Sensible Heating Rate To Zone [W]

This field is the rate of sensible heating in Watts provided to the zone by condenser waste heat rejection, which impacts the zone air heat balance.

Refrigeration Chiller Compressor Rack Sensible Heating Energy To Zone [J]

This field is the sensible heating energy in Joules provided to the zone by condenser waste heat rejection for the timestep being reported.

Refrigeration:Case

The Refrigeration Case object works in conjunction with a compressor rack, a refrigeration system, or a secondary loop object (Refrigeration:CompressorRack, Refrigeration:System, or Refrigeration:SecondarySystem) to simulate the performance of a refrigerated case system. The refrigerated case model uses performance information at rated conditions along with performance curves for latent case credits and defrost heat load to determine performance at

off-rated conditions. Energy use for lights, fans and anti-sweat heaters is modeled based on inputs for nominal power, schedules, and control type. The refrigerated case model accounts for the sensible and latent heat exchange with the surrounding environment (termed "case credits") which impacts the temperature and humidity in the zone where the case is located.

A dataset has been provided containing refrigerated case input data for a large number of refrigerated cases from multiple manufacturers. See *RefrigerationCases.idf*.

The Refrigeration Case object inputs include a case name, an availability schedule name, the zone name for the location of the case, and the temperature and relative humidity of the ambient (zone) air surrounding the refrigerated case at the rating conditions for case performance. Additional inputs include the total cooling capacity, latent heat ratio, and run time fraction of the refrigerated case at rated conditions. The case length and operating temperature (average temperature of air/products within the case) must also be specified.

The refrigerated case model requires two curves to describe performance at off-rated conditions (i.e., at different zone temperature and humidity levels): the latent case credit curve and the defrost energy correction curve. The user must enter cubic performance curves with the independent variable being user selectable (case temperature, zone relative humidity, or zone dewpoint temperature).

The user can select from eight case defrost types, with additional inputs being required depending on the type selected. The user must enter a defrost schedule (unless Case Defrost Type = None), and an optional defrost drip-down schedule can be specified to allow additional time for melted frost to drain from the cooling coil following the regular defrost period.

Inputs are required for case fans, lights, and anti-sweat heaters. Case lighting can be controlled by the user through entering a schedule. The case fans operate whenever the cooling coil is operating and during defrost periods for certain case defrost types. Anti-sweat heater power can be controlled by several methods which are user selectable. The model assumes that the fans are contained within the thermal envelope of the case and provide a direct heat load on the case cooling coil. For lighting and anti-sweat heaters, the user can specify the fraction of their respective heat loads that directly impact the case cooling coil (with the remainder of their heat load impacting the surrounding zone air).

The user has the option of specifying a case restocking schedule and a schedule for modifying the case credits if needed. Finally, the user can specify the under case HVAC return air fraction which determines the portion of the case credits that directly impact the HVAC return air conditions (with the remainder of the case credits impacting the zone sensible and latent loads).

Field: Name

A unique user-assigned name for an instance of a refrigerated case. Any reference to this case by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the case will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the refrigerated case will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, cases require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the case is assumed to be available at all time periods.

Field: Zone Name

The name of the zone where the refrigerated case is located. The refrigerated case will impact the air heat balance in this zone. When modeling multiple refrigerated cases connected to a single compressor rack where the condenser heat is rejected to the zone (ref:

Refrigeration:CompressorRack), all of the refrigerated cases connected to that compressor rack must be located in the same zone.

Field: Rated Ambient Temperature

Dry-bulb temperature of the ambient (zone) air surrounding the refrigerated case at the rating conditions for refrigerated case performance. The default value for this field is 23.9°C (75°F). This temperature must be greater than 0°C and greater than the case operating temperature.

Field: Rated Ambient Relative Humidity

Relative humidity of the ambient (zone) air surrounding the refrigerated case at the rating conditions for refrigerated case performance. The default value for this field is 55% RH.

Field: Rated Total Cooling Capacity per Unit Length

The total, full load cooling capacity (sensible plus latent) in watts per unit length of refrigerated case (W/m) at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, Case Operating Temperature, and with the Standard Case Fan Power per Unit Length and the Standard Case Lighting Power per Unit Length). The value entered for this field must be greater than zero, with a default value of 1900 W/m if the field is blank.

Field: Rated Latent Heat Ratio

The latent heat ratio (LHR=latent capacity divided by total cooling capacity) of the refrigerated case at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, Case Operating Temperature, and with the Standard Case Fan Power per Unit Length and the Standard Case Lighting Power per Unit Length). The value for this field can range from zero to 1.0, with a default value of 0.3 if the field is blank.

Field: Rated Runtime Fraction

The runtime fraction of the refrigerated case at rated conditions (i.e., at the Rated Ambient Temperature, Rated Ambient Relative Humidity, and Case Operating Temperature). Even at rated conditions, refrigerated cases typically include additional cooling capacity to account for product stocking and recovery from defrost. The rated runtime fraction for refrigerated cases typically ranges from 0.8 to 0.9. The entered value for this field must be greater than 0.0 and less than or equal to 1.0, and the default value is 0.85 if the field is blank.

Field: Case Length

The length of the refrigerated case in meters. The entered value for this field must be greater than 0.0, and the default value is 3 meters if the field is blank.

Field: Case Operating Temperature

The average temperature of the air and products within the refrigerated case in °C. The refrigerated case manufacturer typically provides this information in the product literature. Typical operating temperatures for medium temperature cases are 1.6°C to 7.2°C (35°F to 45°F). Typical operating temperatures for low temperatures cases are -28.9°C to -17.8°C (-20°F to 0°F). The entered value for this field must be less than 20°C and lower than the Rated Ambient Temperature. The default value is 1.1°C if the field is blank.

Field: Latent Case Credit Curve Type

This alpha field defines the form of the curve used to modify the latent case credits (latent heat removed from the zone where the refrigerated case is located) at off-rated conditions. The valid choices for this field are:

- CaseTemperatureMethod

This method defines the variation in latent case credits as a cubic function of Case Operating Temperature. The result from the cubic curve is multiplied by the difference between the rated ambient relative humidity and the actual zone relative

humidity, and one minus this value is multiplied by the Rated LHR to give the operating LHR at the actual zone humidity condition. (Representative coefficient values for single-shelf horizontal and multi-shelf vertical display cases are given in the EnergyPlus Engineering Reference.)

- **RelativeHumidityMethod**

This method defines the variation in latent case credits as a cubic function of ambient (zone) air relative humidity.

- **DewpointMethod**

This method defines the variation in latent case credits as a cubic function of ambient (zone) air dewpoint temperature.

The default curve type is the Case Temperature Method. Refer to the Engineering Reference for further information on how latent case credits are modeled.

Field: Latent Case Credit Curve Name

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the latent case credits at off-rated conditions. The curve should be normalized to have a value of 1.0 at the rated ambient air conditions defined above.

Field: Standard Case Fan Power per Unit Length

The total standard fan power in Watts per unit length of refrigerated case (W/m). This value represents the fan power included in the field Rated Total Cooling Capacity per Unit Length, and is used to determine the sensible case credits. The entered value for this field must be greater than or equal to zero, and the default value is 75.0 W/m if the field is blank.

Field: Operating Case Fan Power per Unit Length

The total operating fan power in Watts per unit length of refrigerated case (W/m). Enter the actual power for the installed fans. The entered value for this field must be greater than or equal to zero, and the value is set equal to the standard case fan powers if the field is blank.

Field: Standard Case Lighting Power per Unit Length

The total standard lighting power in Watts per unit length of refrigerated case (W/m). This value should represent the lighting power provided by the case manufacturer and included in the “Rated Total Cooling Capacity per Unit Length” field and is used to determine the sensible case credits. For cases where the manufacturer does not include the lights in the Rated Total Cooling Capacity, this value should be zero (0.0). The entered value for this field must be greater than or equal to zero, and the default value is 90.0 W/m if the field is blank.

Field: Installed Case Lighting Power per Unit Length

The total installed lighting power in Watts per unit length of refrigerated case (W/m). Enter the actual power for the installed lights. This number may be greater or less than the standard lighting power value, depending upon the manufacturer’s practice in specifying the case rated cooling capacity and whether or not energy-efficient lights are being modeled. The next field (i.e. Case Lighting Schedule Name) may be used to specify the name of a schedule that contains the fraction of the Installed Case Lighting Power per Unit Length to be modeled for each timestep of the simulation period. The entered value for this field must be greater than or equal to zero, and the value is set equal to the standard case lighting power if the field is blank.

Field: Case Lighting Schedule Name

The name of the schedule (ref: Schedule) that denotes the fraction of installed refrigerated case lights that operate during a given time period. A schedule value greater than 0 indicates that the lights will operate during that time period (maximum schedule value of 1.0 means lights are fully on at the Installed Case Lighting Power per Unit Length level). A schedule value of zero denotes that the lights are off. The refrigerated case lights will typically operate

only when the store is open for business and can be scheduled off as desired via this schedule. If this field is left blank, the default schedule has a value of 1 for all time periods.

Field: Fraction of Lighting Energy To Case

The fraction of the lighting energy that directly contributes to the case heat load. The remainder of the lighting energy ($1 - \text{fraction}$) is a heating load to the zone where the case is located. This field can be used to model lighting ballasts and bulbs located outside the air curtain of the refrigerated case. The value for this field can range from zero to 1.0, with a default value of 1.0 if the field is blank.

Field: Case Anti-Sweat Heater Power per Unit Length

The electric anti-sweat heater power in watts per unit length of refrigerated case (W/m). The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

Field: Minimum Anti-Sweat Heater Power per Unit Length

The minimum electric anti-sweat heater power in watts per unit length of refrigerated case (W/m). Anti-sweat heater power will remain at or above this value for anti-sweat heater control types linear, dewpoint method, or heat balance method. Other anti-sweat heater control types disregard this field. The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

Field: Anti-Sweat Heater Control Type

The type of anti-sweat heater control used for this refrigerated case. Valid choices are None, Constant, Linear, DewpointMethod, or HeatBalanceMethod. The default is None if the field is blank. Refer to the Engineering Reference for further information on how the different anti-sweat heater controls are modeled.

Field: Humidity at Zero Anti-Sweat Heater Energy

The value of this numeric field is only used when the Linear anti-sweat heater control type is selected. Enter the zone relative humidity where anti-sweat heater energy use is zero. Negative values for relative humidity may be entered. Other anti-sweat heater control types disregard this field. The value entered for this field must be less than the Rated Ambient Relative Humidity specified above. The default for this field is -10.0.

Field: Case Height

The value of this numeric field is used when Heat Balance Method anti-sweat heater control is selected. Enter the case height in meters. Other anti-sweat heater control types disregard this field. The entered value for this field must be greater than zero when Heat Balance Method anti-sweat heater control is selected, and the default value is 1.5 meters if the field is blank.

Field: Fraction of Anti-Sweat Heater Energy To Case

This value denotes the fraction of anti-sweat heater energy that results in a direct heat load to the refrigerated case. The remainder of the anti-sweat heater energy ($1 - \text{fraction}$) is a heating load to the zone where the refrigerated case is located. The value for this field can range from zero to 1.0, with a default value of 1.0 if the field is blank.

Field: Case Defrost Power per Unit Length

The defrost power in watts per unit length of refrigerated case (W/m). This input is required for hot-gas, hot-fluid, or electric defrost types and is used to evaluate the load on the case as well as power or heat consumption. Refrigerated case manufacturers do not typically provide information on the heat input for hot-gas and hot-fluid defrost. Information provided for electric defrost power can be substituted here for refrigerated cases using hot-gas or hot-fluid defrost if other information is not available. Only electric Case Defrost Types consume

electricity during the defrost period. The entered value for this field must be greater than or equal to zero, and the default value is 0 W/m if the field is blank.

Field: Case Defrost Type

The type of defrost used for this refrigerated case. Valid choices are None, OffCycle, HotGas, HotGaswithTemperatureTermination, Electric, ElectricwithTemperatureTermination, HotFluid, and HotFluidwithTemperatureTermination. The default defrost type is OffCycle if the field is blank. Refer to the Engineering Reference for further information on how the different case defrost types are modeled. In particular, hot-fluid defrost systems may be effective with much shorter defrost times than other systems, which should be reflected in the defrost and drip-down schedules.

Field: Case Defrost Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case requires defrosting. A schedule value of 1.0 indicates that defrost will be on during a given time period. A value equal to 0 denotes that the defrost is off. Defrost schedules normally repeat the duration and number of defrost cycles for each day of the year. The refrigerated case manufacturer typically provides this information with the product literature. The use of Compact Schedules (ref. Schedules) are ideal for this purpose. In a typical supermarket with many cases, it is important to diversify the defrost schedules in order to avoid large swings in the load placed upon the remainder of the refrigeration system.

Field: Case Defrost Drip-Down Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case requires additional time for draining condensate after the defrost period. A schedule value of 1.0 indicates that the defrost drip-down period is on during a given time period. A value equal to 0 denotes that the defrost drip-down period is over. The refrigerated case manufacturer typically provides this information with the product literature.

Each defrost drip-down period specified in this schedule should start at the same time as the corresponding defrost period specified in the schedule for Case Defrost Schedule, and the drip-down schedule defrost period should always be longer than or equal to the length of the defrost schedule time period. For example, if the case defrost schedule contains a defrost period from 7:00 to 7:15, you would specify a case defrost drip-down period from 7:00 to 7:20 if you wanted to model a 5 minute condensate drip-down period after the regular defrost period. If no drip-down schedule is entered, then the case defrost schedule (specified for the previous input field) will be used. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

Field: Defrost Energy Correction Curve Type

This alpha field defines the form of the correction curve used to modify the defrost energy use (and the associated load on the case cooling coil) at off-rated conditions. The valid choices for this field are:

- **None**
This choice specifies that a defrost energy correction curve will not be used.
- **CaseTemperatureMethod**
This method defines the variation in defrost energy as a cubic function of Case Operating Temperature. The result from the cubic curve is multiplied by the difference between the rated ambient relative humidity and the actual zone relative humidity, and one minus this value is multiplied by the Case Defrost Power to give the (average) operating defrost power at the actual zone humidity condition. (Representative coefficient values for single-shelf horizontal and multi-shelf vertical display cases are given in the EnergyPlus Engineering Reference.)
- **RelativeHumidityMethod**

- This method defines the variation in defrost energy as a cubic function of ambient (zone) air relative humidity.
- DewpointMethod
This method defines the variation in defrost energy as a cubic function of ambient (zone) air dewpoint temperature.

The default curve type is None. The methods described here (e.g. Case Temperature, Relative Humidity, and Dewpoint) are applicable only to Electric with Temperature Termination, Hot-Gas with Temperature Termination, and Hot-Brine with Temperature Termination case defrost types. Refer to the Engineering Reference for further information on how the defrost energy correction types are modeled.

Field: Defrost Energy Correction Curve Name

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the defrost energy (and the associated load on the case cooling coil) at off-rated conditions. The curve should be normalized to have the value of 1.0 at the rated ambient air conditions defined above. The defrost energy correction curve name is used only for the Electric with Temperature Termination, Hot-Gas with Temperature Termination, and Hot-Brine with Temperature Termination case defrost types.

Field: Under Case HVAC Return Air Fraction

This field denotes the fraction of HVAC system (air loop) return air that passes beneath the refrigerated case, if any. At times it is necessary to design HVAC systems with under case returns to avoid overcooling the area around the refrigerated case, thus providing a more comfortable environment for the zone occupants. This return air fraction affects the portion of the case credits (sensible and latent) that are applied to the air returning to the HVAC system, while the remainder of the case credits directly impacts the zone air heat balance. Refer to the Engineering Reference for further information on how this is modeled. The sum of the Under Case HVAC Return Air Fractions for all refrigerated cases located in a single zone must be less than or equal to 1.0. The value for this field can range from zero to 1.0, with a default value of 0 if the field is blank.

Field: Refrigerated Case Restocking Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigerated case is being restocked with product. The schedule should contain values in units of Watts per unit length of refrigerated case (W/m). This field can be used to denote the additional load imposed on the refrigerated case from stocking the case with product that is warmer than the refrigerated case temperature. This information is difficult to find and may require additional research for proper modeling; however, this schedule is available for this purpose if desired. If restocking of the refrigerated case will not be simulated, enter a schedule with values of zero for all time periods or leave this field blank.

Field: Case Credit Fraction Schedule Name

The name of the schedule (ref: Schedule) that denotes a fraction of both the sensible and latent case credits to be applied to the zone and/or the HVAC system return air. Schedule values must be from 0 to 1. This allows correction of the case credits for various refrigerated case types. For instance, if glass door refrigerated display cases are installed in a store that is operated 12 hours per day, then the doors will remain closed during the unoccupied times and would therefore reduce the sensible and latent case credits during the unoccupied time. Leaving this field blank will result in no case credit fraction being applied during the simulation.

Field: Design Evaporator Temperature or Brine Inlet Temperature

The value of this numeric field is used only with the detailed refrigeration system and is not read for the compressor-rack system. For the refrigeration system, it is used to evaluate compressor performance and is also used when the evaporator pressure and temperature

are allowed to float at loads less than the design load. If the case is cooled by a secondary system (ref: Refrigeration:SecondarySystem), this value is the brine inlet temperature. The minimum value is -70C and the maximum value is 40C. The default value is 5C less than the case temperature.

Field: Average Refrigerant Charge Inventory

The value of this optional field is the refrigerant inventory present in the refrigerated case during ordinary operation. The value is used to produce an estimate of the total refrigerant present in the refrigeration system. The value is entered in kg/m.

The following is an example input for a refrigerated case.

Refrigerated Case Evaporator Total Heat Transfer Rate [W]

This field is the total (sensible plus latent) cooling rate of the refrigerated case evaporator coil in Watts.

Refrigerated Case Evaporator Total Heat Transfer Energy [J]

This field is the total (sensible plus latent) cooling of the refrigerated case evaporator coil in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Refrigerated Case Evaporator Sensible Heat Transfer Rate [W]

This field is the sensible cooling rate of the refrigerated case evaporator coil in Watts.

Refrigerated Case Evaporator Sensible Heat Transfer Energy [J]

This field is the sensible cooling of the refrigerated case evaporator coil in Joules over the timestep being reported.

Refrigerated Case Evaporator Latent Heat Transfer Rate [W]

This field is the latent cooling (dehumidification) rate of the refrigerated case evaporator coil in Watts.

Refrigerated Case Evaporator Latent Heat Transfer [J]

This field is the latent cooling (dehumidification) of the refrigerated case evaporator coil in Joules over the timestep being reported.

Refrigerated Case Sensible Cooling Zone Credit Rate [W]

This field is the rate of sensible cooling case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

Refrigerated Case Sensible Cooling Zone Credit Energy [J]

This field is the amount of sensible cooling case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

Refrigerated Case Sensible Heating Zone Credit Rate [W]

This field is the rate of sensible heating case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

Refrigerated Case Sensible Heating Zone Credit Energy [J]

This field is the amount of sensible heating case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the sensible case credits are applied to the zone. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

Refrigerated Case Latent Zone Credit Rate [W]

This field is the rate of latent cooling (dehumidification) case credits delivered to the zone in Watts. If an under case return duct is simulated, only a portion of the latent case credits are applied to the zone. A negative value (or zero) will be reported when the refrigerated case provides dehumidification (thereby reducing the zone latent load).

Refrigerated Case Latent Zone Credit Energy [J]

This field is the amount of latent cooling (dehumidification) case credit energy delivered to the zone in Joules. If an under case return duct is simulated, only a portion of the latent case credits are applied to the zone. A negative value (or zero) will be reported when the refrigerated case provides dehumidification (thereby reducing the zone latent load).

Refrigerated Case Sensible Cooling HVAC RA Credit Rate [W]

This field is the rate of sensible cooling case credits delivered to the return air duct (zone return air node) in Watts. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is cooled by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible cooling is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Sensible Cooling HVAC RA Credit Energy [J]

This field is the amount of sensible cooling case credit energy delivered to the return air duct (zone return air node) in Joules. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is cooled by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible cooling is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Sensible Heating HVAC RA Credit Rate [W]

This field is the rate of sensible heating case credits delivered to the return air duct (zone return air node) in Watts. If an under case return duct is simulated, a portion of the sensible case credits are applied to the HVAC (zone) return air. A positive value is reported when the return air is heated by sensible case credits, otherwise a zero is reported. If the HVAC system is off for a simulation timestep (no return air mass flow), then this sensible heating is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Sensible Heating HVAC RA Credit Energy [J]

This field is the amount of sensible heating case credit energy delivered to the return air duct (thereby reducing the zone latent load). If the HVAC system is off for a simulation timestep (no return air mass flow), then this latent energy is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Latent HVAC RA Credit Energy [J]

This field is the amount of latent cooling (dehumidification) case credit energy delivered to the return air duct (zone return air node) in Joules. If an under case return duct is simulated, only a portion of the latent case credits are applied to the HVAC (zone) return air. A negative value (or zero) will be reported since the refrigerated case provides dehumidification (thereby reducing the zone latent load). If the HVAC system is off for a simulation timestep (no return air mass flow), then this latent energy is actually provided to the zone air instead (even though a non-zero value is reported here).

Refrigerated Case Evaporator Fan Electric Power [W]

This field is the electric power input to the refrigerated case fan(s) in Watts.

Refrigerated Case Evaporator Fan Electric Consumption [J]

This field is the electricity consumption of the refrigerated case fan(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Refrigerated Case Lighting Electric Power [W]

This field is the electric power input to the refrigerated case lights in Watts.

Refrigerated Case Lighting Electric Consumption [J]

This field is the electricity consumption of the refrigerated case lights in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Refrigerated Case Defrost Energy Correction Curve Value

This field is the output of the Defrost Energy Correction Curve which denotes the variation in defrost energy at off-rated conditions. The output of the defrost energy correction curve directly impacts the energy used during the defrost time period. It does not, however, impact the duration of the defrost period. This output is available only for Electric with Temperature Termination, Hot-Gas with Temperature Termination, or Hot-Brine with Temperature Termination case defrost types.

Refrigerated Case Latent Case Credit Curve Value

This field is the output of the Latent Case Credit Curve which denotes the variation in latent case credits at off-rated conditions. The output of the latent case credit curve directly impacts the amount of frost formation on the refrigerated case evaporator coil and the requirement for defrost.

Refrigerated Case Anti-Sweat Electric Power [W]

This field is the electric power input to the refrigerated case anti-sweat heater in Watts. This output is available unless anti-sweat heater control type is specified as NONE.

Refrigerated Case Anti-Sweat Electric Consumption [J]

This field is the total electricity consumption of the refrigerated case anti-sweat heater in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter). This output is available unless anti-sweat heater control type is specified as NONE.

Refrigerated Case Defrost Electric Power [W]

This field is the electric power input to the refrigerated case electric defrost heater(s) in Watts. This output is available if case defrost type is Electric or Electric with Temperature Termination.

Refrigerated Case Defrost Electric Consumption [J]

This field is the total electricity consumption of the refrigerated case electric defrost heater(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter). This output is available if case defrost type is Electric or Electric with Temperature Termination.

Refrigeration:CaseAndWalkInList

This object provides a list of all the refrigerated cases and/or walk in coolers cooled by a single refrigeration system (ref: Refrigeration:CompressorRack and Refrigeration:System). This list is extensible. Note that the names of all cases, walk-ins, air chillers, and caseandwalkinlists must be unique. That is, you cannot give a list the same name as one of the cases. Similarly, a walkin cannot have the same name as a case. This list may contain a combination of case and walk-in names OR a list of air chiller names. Air chillers may not be included in any list that also includes cases or walk-ins.

Field: Name

A unique user-assigned name for an instance of a CaseAndWalkInList. Any reference to this list by another object will use this name.

Field: Case or WalkIn or Air Chiller <x> Name

Identifies a particular refrigerated case or walk-in. The name will be validated against the Refrigeration Case, Refrigeration WalkIn, and Air Chiller names (ref: Refrigeration:Case, Refrigeration:WalkIn, and Refrigeration:AirChiller) in the input file. Up to 20 are provided in the IDD; this object is extensible.

The following is an example input for a CaseAndWalkInList.

```
Refrigeration:CaseAndWalkInList,
  MediumTempCaselist,      !- Name
  UprightDairyCase,        !- Refrigeration Case or WalkIn Name #1
  LunchmeatCase,           !- Refrigeration Case or WalkIn Name #2
  MeatWalkIn,              !- Refrigeration Case or WalkIn Name #3
  DeliCaseOne;             !- Refrigeration Case or WalkIn Name #4
```

Refrigeration:WalkIn

The Refrigeration WalkIn object works in conjunction with a compressor rack, a refrigeration system, or a refrigeration secondary system object (Ref. Refrigeration:CompressorRack, Refrigeration:System, or Refrigeration:SecondarySystem) to simulate the performance of a walk-in cooler. The walk-in cooler model uses information at rated conditions along with input descriptions for heat transfer surfaces facing multiple zones to determine performance. Energy use for lights, fans, and floor and anti-sweat heaters is modeled based on inputs for nominal power, schedules, and control type. The walk-in cooler model accounts for the sensible and latent heat exchange with the surrounding environment (termed "case credits") which impacts the temperature and humidity in each zone adjacent to the walk-in.

The walk-in cooler object inputs include a name, an availability schedule name, the rated cooling capacity, the rated operating temperature, the rated cooling source temperature, the rated total heating power and heating power schedule, the rated fan and lighting power and schedules, defrost type, defrost control type, defrost schedule name, drip-down schedule name, defrost power, the portion of the defrost energy used to melt ice (only for temperature termination control type), restocking schedule, refrigerant inventory, and the floor area and U-value.

For each zone adjacent to the walk-in, the user must input the zone name and the insulated surface area and U-value facing that zone. The user must also specify, for two types of doors, the door area, height, U-value, door opening schedule name, and any door opening protection.

Under case HVAC return air fraction, available for refrigerated cases, is not available for walk-in coolers.

Field: Name

A unique user-assigned name for an instance of a refrigerated walk-in. Any reference to this walk-in by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the walk in can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the walkin will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the walkin will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, walkins require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the default schedule has a value of 1 for all time periods.

Field: Rated Coil Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts (W) at rated conditions The value entered for this field must be greater than zero, with no default value.

Field: Operating Temperature

The rated average temperature of the air and products within the walk-in cooler in °C. The entered value for this field must be less than 20°C. There is no default value.

Field: Rated Cooling Source Temperature

For a DX evaporator coil, enter the saturated evaporating temperature in °C. For a fluid coil, enter the fluid coil entrance temperature in °C. There is no default value. This number is used, with temperatures for other refrigeration loads on any one system, to set that system's minimum suction pressure or minimum circulating fluid temperature. (This value is not used if the walkin is cooled by a compressor rack object.)

Field: Rated Total Heating Power

The total heating power in watts including all anti-sweat, door, drip-pan, and floor heaters (W). This value is required and has no default value.

Field: Heating Power Schedule Name

The name of the schedule (ref: Schedule) that denotes the fraction of heater power that operates during a given time period. A schedule value of zero denotes that all heaters are off. A schedule value greater than 0 indicates that some portion of the total heater power will operate during that time period (maximum schedule value of 1.0 means all heaters are fully on). For example, if door and floor heaters represent 50% of the total heater power and are on all the time, the minimum schedule value would be 0.5. If anti-sweat heaters represent 40% of the total heater power and are only on during certain hours, the schedule value during those hours would be increased by 0.4. If this field is left blank, the default schedule has a value of 1 for all time periods.

Field: Rated Cooling Coil Fan Power

The cooling coil fan power in watts (W). This value has a default value of 375W. This fan is assumed to run continuously except during electric, hot brine, or hot gas defrost periods.

Field: Rated Circulation Fan Power

The circulation fan power in watts (W). This value has a default value of 0 W. This fan is assumed to run continuously.

Field: Rated Total Lighting Power

The total lighting power in watts including both display and task lighting (W). This value is required and has no default value.

Field: Lighting Schedule Name

The name of the schedule (ref: Schedule) that denotes the fraction of walk-in lights that operate during a given time period. A schedule value greater than 0 indicates that the lights will operate during that time period (maximum schedule value of 1.0 means lights are fully on). A schedule value of zero denotes that the lights are off. If this field is left blank, the default schedule has a value of 1 for all time periods.

Field: Defrost Type

The type of defrost used for this walk-in. Valid choices are None, Off-Cycle, HotFluid, and Electric. The default defrost type is Electric if the field is blank. HotFluid includes both hot gas and hot brine defrost systems. Refer to the Engineering Reference for further information on how the different defrost types are modeled.

Field: Defrost Control Type

The type of defrost control used for this walkin. Valid choices are TimeSchedule and TemperatureTermination. The default is TimeSchedule if the field is blank. Refer to the Engineering Reference for further information on how the different defrost controls are modeled.

Field: Defrost Schedule Name

The name of the schedule (ref: Schedule) that denotes when the walkin requires defrosting. A schedule value of 1.0 indicates that defrost will be on during a given time period if the defrost control type is "TimeSchedule". For the TemperatureTermination defrost control type, the defrost will start with the schedule value changes from 0 to 1, but will end when the ice is melted. A value equal to 0 denotes that the defrost is off. Defrost schedules normally repeat the duration and number of defrost cycles for each day of the year. The walkin manufacturer typically provides this information with the product literature. If TemperatureTermination control type is used, the defrost schedule is used for the defrost cycle start time and the defrost cycle end time is not allowed to extend beyond the scheduled off time. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

Field: Defrost Drip-Down Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the walkin requires additional time for draining condensate after the defrost period. A schedule value of 1.0 indicates that the defrost drip-down period is on during a given time period. A value equal to 0 denotes that the defrost drip-down period is over. The walkin manufacturer typically provides this information with the product literature.

Each defrost drip-down period specified in this schedule should start at the same time as the corresponding defrost period specified in the schedule for Defrost Schedule, and the drip-down schedule defrost period should always be longer than or equal to the length of the defrost schedule time period. For example, if the defrost schedule contains a defrost period from 7:00 to 7:15, you would specify a case defrost drip-down period from 7:00 to 7:20 if you wanted to model a 5 minute condensate drip-down period after the regular defrost period. If no drip-down schedule is entered, then the defrost schedule (specified for the previous input field) will be used. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

Field: Defrost Power

The defrost power in watts. This input is required for hot-fluid (hot gas or hot brine), or electric defrost types. Walkin manufacturers do not typically provide information on the heat input for hot gas and hot brine defrost. Information provided for electric defrost power can be substituted here for walkins using hot-gas or hot-brine defrost if other information is not

available. Only electric Defrost Types consume electricity during the defrost period. The entered value for this field must be greater than or equal to zero.

Field: Temperature Termination Defrost Fraction to Ice

When cooling coils go through a defrost cycle, only a portion of the defrost energy is actually used to melt the ice. The rest of the defrost energy goes to increasing the temperature of the coils themselves and to the walkin environment. The Temperature Termination defrost control type calculates the end of the defrost cycle that corresponds to melting all the ice. Therefore, the user must input this fractional value. The default value is 0.7 for electric defrost and 0.3 for hot fluid defrost. Refer to the Engineering Reference for further information on how the defrost energy control types are modeled.

Field: Restocking Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the walkin is being restocked with product. The schedule should contain values in units of Watts (note this is different from the restocking schedule values for cases that are entered per unit length). This field can be used to denote the additional load imposed on the walkin from stocking the walkin with product that is warmer than the walkin temperature. This information is difficult to find and may require additional research for proper modeling; however, this schedule is available for this purpose if desired. If restocking of the refrigerated walkin will not be simulated, enter a schedule with values of zero for all time periods or leave this field blank.

Field: Average Refrigerant Charge Inventory

The value of this optional field is the refrigerant inventory present in the walkin during ordinary operation. The value is used to produce an estimate of the total refrigerant present in the refrigeration system. The value is entered in kg.

Field: Insulated Floor Surface Area

The floor area in square meters. This value is required and has no default value.

Field: Insulated Floor U-Value

The floor thermal transmittance (in W/m²-K). This value has a default value of 0.3154. (This corresponds to R18 in Archaic American Insulation Units. To convert other R-values to thermal transmittance, divide 5.678 by the R-value. For example, R15 is 0.3785 W/m²-K and R5 is 1.136 W/m²-K.)

THE REMAINING 12 FIELDS FOR THE WALK-IN COOLER MUST BE REPEATED FOR EACH ZONE WHICH IS IN CONTACT WITH A WALK-IN WALL, CEILING, OR DOOR. The IDD includes fields for 3 zones, but can be extended by repeating the last 12 values in the object.

Field: Zone <x> Name

The name of a zone adjoining the walkin. The walkin will impact the air heat balance in this zone. This zone must represent a conditioned space, that is, it must appear in a ZoneHVAC:EquipmentConnections object.

Field: Total Insulated Surface Area Facing Zone <x>

The total surface area (walls and ceilings) facing this particular zone in square meters. This value is required and has no default value.

Field: Insulated Surface U-Value Facing Zone <x>

The surface (walls and ceilings) thermal transmittance (in W/m²-K). This value has a default value of 0.3154. (This corresponds to R18 in Archaic American Insulation Units. To convert other R-values to thermal transmittance, divide 5.678 by the R-value. For example, R15 is 0.3785 W/m²-K and R5 is 1.136 W/m²-K.)

Field: Area of Glass Reach In Doors Facing Zone <x>

The total area of glass doors facing this particular zone in square meters. The default is 0.0.

Field: Height of Glass Reach In Doors Facing Zone <x>

The glass reach in door height in meters. The default is 1.5.

Field: Glass Reach In Door U-Value Facing Zone <x>

The glass door thermal transmittance (in W/m²-K). This field has a default value of 1.136. (This corresponds to R5 in Archaic American Insulation Units.)

Field: Glass Reach In Door Opening Schedule Name Facing Zone <x>

The name of the schedule (ref: Schedule) that denotes the fraction of time glass doors are open during a given time period. The schedule values should be between 0 and 1.0. If no schedule is specified, the doors are assumed to be open 5% of the time (corresponding to a schedule value of 0.05).

Field: Area of Stocking Doors Facing Zone <x>

The total area of stock doors facing this particular zone in square meters. The default is 0.0.

Field: Height of Stocking Doors Facing Zone <x>

The stocking door height in meters. The default is 2.0.

Field: Stocking Door U-Value Facing Zone <x>

The stocking door thermal transmittance (in W/m²-K). This value has a default value of 0.3785. (This corresponds to R15 in Archaic American Insulation Units.)

Field: Stocking Door Opening Schedule Name Facing Zone <x>

The name of the schedule (ref: Schedule) that denotes the fraction of time stocking doors are open during a given time period. The schedule values should be between 0 and 1.0. If no schedule is specified, the doors are assumed to be open 5% of the time (corresponding to a schedule value of 0.05).

Field: Stocking Door Opening Protection Type Facing Zone <x>

The type of stocking door opening protection used for this walkin. Valid choices are None, AirCurtain, and StripCurtain. The default is AirCurtain if the field is blank. Use the type, StripCurtain, for both hanging strips and airlock vestibules. Refer to the Engineering Reference for further information on how the door protection types are modeled.

The following is an example input for a refrigeration walkin.

Walk In Evaporator Total Heat Transfer Rate [W]

This field is the total (sensible plus latent) cooling rate of the WalkIn evaporator coil in Watts.

Walk In Evaporator Total Heat Transfer Energy [J]

This field is the total (sensible plus latent) cooling of the WalkIn evaporator coil in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Walk In Total Sensible Heat Transfer Rate [W]

This field is the sensible cooling rate of the WalkIn evaporator coil in Watts.

Walk In Total Sensible Heat Transfer Energy [J]

This field is the sensible cooling of the WalkIn evaporator coil in Joules over the timestep being reported.

Walk In Total Latent Heat Transfer Rate [W]

This field is the latent cooling (dehumidification) rate of the WalkIn evaporator coil in Watts.

Walk In Total Latent Heat Transfer Energy [J]

This field is the latent cooling (dehumidification) of the WalkIn evaporator coil in Joules over the timestep being reported.

Walk In Total Auxiliary Electric Power [W]

This field is the total electricity (fan, heaters, lights, and electric defrost) used by the walkin in Watts.

Walk In Total Auxiliary Electric Consumption [J]

This field is the electricity (fan, heaters, lights, and electric defrost)used by the WalkIn in Joules over the timestep being reported.

Walk In Fans Electric Power [W]

This field is the electric power input to the WalkIn fan(s) in Watts.

Walk In Fan Electric Consumption [J]

This field is the electricity consumption of the WalkIn fan(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Walk In Lighting Electric Power [W]

This field is the electric power input to the WalkIn lights in Watts.

Walk In Lighting Electric Consumption [J]

This field is the electricity consumption of the WalkIn lights in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Walk In Heaters Electric Power [W]

This field is the electric power input to the WalkIn heaters in Watts.

Walk In Heaters Electric Consumption [J]

This field is the total electricity consumption of the WalkIn heaters in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Walk In Defrost Electric Power [W]

This field is the electric power input to the WalkIn electric defrost heater(s) in Watts. This output is available if case defrost type is Electric.

Walk In Defrost Electric Consumption [J]

This field is the total electricity consumption of the WalkIn electric defrost heater(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter). This output is available if case defrost type is Electric.

The following output variables are available for each zone adjacent to the walkin. An output variable identification is created for each zone exchanging energy with the walkin. For example if the walkin, “DairyWalkIn”, were exchanging energy with the zone, “SalesArea”, the output variable identification would be “DairyWalkInInZoneSalesArea”.

Zone/Walk In Sensible Cooling Zone Credit Rate [W]

This field is the rate of sensible cooling case credits delivered to the zone in Watts. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

Zone/Walk In Sensible Cooling Zone Credit Energy [J]

This field is the amount of sensible cooling case credit energy delivered to the zone in Joules. A positive value is reported when the zone is cooled by sensible case credits, otherwise a zero is reported.

Zone/Walk In Sensible Heating Zone Credit Rate [W]

This field is the rate of sensible heating case credits delivered to the zone in Watts. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

Zone/Walk In Sensible Heating Zone Credit Energy [J]

This field is the amount of sensible heating case credit energy delivered to the zone in Joules. A positive value is reported when the zone is heated by sensible case credits, otherwise a zero is reported.

Zone/Walk In Latent Zone Credit Rate [W]

This field is the rate of latent cooling (dehumidification) case credits delivered to the zone in Watts. A negative value (or zero) will be reported when the WalkIn provides dehumidification (thereby reducing the zone latent load).

Zone/Walk In Latent Zone Credit Energy [J]

This field is the amount of latent cooling (dehumidification) case credit energy delivered to the zone in Joules. A negative value (or zero) will be reported when the WalkIn provides dehumidification (thereby reducing the zone latent load).

Refrigeration:System

The refrigeration system object simulates the performance of a supermarket refrigeration system when used along with other objects to define the refrigeration load(s), the compressor(s), and the condenser.

At least one refrigeration load object must be defined which may be one of four types of load, a refrigerated case, a walk-in cooler, a chiller providing refrigeration to a secondary loop, or a cascade condenser which absorbs heat rejected by a lower-temperature system (Ref. Refrigeration:Case, Refrigeration:WalkIn, Refrigeration:SecondarySystem, and Refrigeration:Condenser:Cascade) If multiple loads are served by the same system , the user should use one or both of the list objects available to assign loads to the system. The first list

includes all cases and walkins cooled directly by this system (Ref. Refrigeration:CaseAndWalkInList). The second list includes any ‘transfer’ loads, that is refrigeration loads borne by this system that are transferred from another refrigeration system via either a secondary loop chiller or a cascade condenser (Ref. Refrigeration:TransferLoadList, see the Engineering Reference for more information about these types of systems).

The refrigeration system object is capable of modeling both single-stage and two-stage compression refrigeration systems. The name of at least one compressor must be defined and a list object is available if the system is served by more than one compressor (Ref. Refrigeration:Compressor and Refrigeration:CompressorList).

Heat is rejected outdoors in a condenser by direct air flow, evaporative water cooling, by a water-cooled condenser with appropriate plant loop piping, or to a cascade condenser cooled by another refrigeration system (ref: Refrigeration:Condenser:AirCooled, Refrigeration:Condenser:EvaporativeCooled, Refrigeration:Condenser:WaterCooled, Refrigeration:Condenser:Cascade). With evaporative cooling, water is sprayed through the air stream to effectively lower the air temperature experienced by the condenser coil as a result of water evaporation. The use of a water-cooled condenser requires the definition of a plant loop to supply cooling to the condenser. If a cascade condenser is specified, the refrigeration system absorbing the rejected heat must also be defined.

The refrigeration system may also include a liquid suction and/or mechanical subcooler (Ref. Refrigeration:Subcooler).

The system object coordinates the energy flows between the other refrigeration objects and is used to set system parameters. Compressor waste heat can also be reclaimed for use by an optional air- or water-heating coil (Ref. Coil:Heating:Desuperheater and Coil:WaterHeating:Desuperheater).

The inputs for the refrigeration system object, in addition to the names of the other refrigeration objects described above, include a name for this system, the minimum condensing temperature, the refrigeration system working fluid, and the type of saturated suction temperature control. Optional input fields are also provided for users seeking to keep track of refrigerant inventory and suction pipe heat gains.

Field: Name

A unique user-assigned name for an instance of a refrigeration system. Any reference to this refrigeration system by another object will use this name.

Field: Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, a single walkin, single air chiller, or a particular list of refrigerated cases and walkins or air chillers, that is cooled by this refrigeration system. The name will be validated against the case, walkin, air chiller and CaseAndWalkInList names (ref: Refrigeration:Case, Refrigeration:WalkIn, Refrigeration:AirChiller, and Refrigeration:CaseAndWalkInList) in the input file. Only cases and walkins or air chillers served directly by the system should be included in this list. Any cases, walkins, or air chillers served indirectly via a secondary loop should NOT be included in this list. Note that any system that serves an air chiller cannot also serve a case or walkin.

Field: Refrigeration Transfer Load or TransferLoad List Name

Identifies a single SecondarySystem, a single Cascade Condenser, OR or a list of Transfer Loads (where the list is comprised of SecondarySystems and/or Cascade Condensers) that are cooled by this refrigeration system. The name will be validated against the secondary system, cascade condenser, and TransferLoad list names (ref: Refrigeration:SecondarySystem, Refrigeration:Condenser:Cascade, and Refrigeration:TransferLoadList) in the input file. Only secondary systems and cascade condensers served directly by the system should be included in this list. (NOTE – this entry is

for a cascade condenser cooled by this system, not a condenser absorbing heat rejected by this system.)

Field: Condenser Name

The name of the condenser that is used to *reject heat from* this refrigeration system. The name will be validated against the condenser names (ref: Refrigeration:Condenser:AirCooled, Refrigeration:Condenser:WaterCooled, Refrigeration:Condenser:EvaporativeCooled, and Refrigeration:Condenser:Cascade) in the input file.

Field:Compressor or Compressor List Name

Identifies a single compressor, or a particular list of compressors, that provide cooling energy to this refrigeration system. The name will be validated against the compressor list names (ref: List:Refrigeration:Compressors) in the input file. If the refrigeration systems contains two stages of compression, this field identifies the low-stage compressors connected to the two-stage system.

Field: Minimum Condensing Temperature

This numeric field specifies the minimum condensing temperature (C), which is usually determined by the temperature required to maintain acceptable thermal expansion valve performance.

Field: Refrigeration System Working Fluid Type

The type of refrigerant used by the system. Valid choices are R11, R123, R134A, R12, R22, R404A, R507A, or R410A. This name will be validated against Fluid Names (ref: Fluid Properties section) in the input file. Note that the corresponding property data, available in FluidPropertiesRefData.idf, must be supplied in the input file.

Field: Suction Temperature Control Type

The type of saturated suction temperature control used by the system. Valid choices are **FloatSuctionTemperature** and **ConstantSuctionTemperature**. If the field is blank, the default will be **ConstantSuctionTemperature**. See the Engineering Reference section, Variable Evaporator Temperature, for a discussion of this option.

Field: Mechanical Subcooler Name

This optional field identifies a mechanical subcooler that absorbs heat from this refrigeration system. This field should not be used for a mechanical subcooler that absorbs heat from another system. The name will be validated against the subcooler names (ref: Refrigeration:Subcooler) in the input file.

Field: Liquid Suction Heat Exchanger Subcooler Name

This optional field Identifies a particular liquid suction heat exchanger (LSHX) subcooler present in this refrigeration system. The name will be validated against the subcooler names (ref: Refrigeration:Subcooler) in the input file.

Field: Sum UA Suction Piping

This optional field is typically used when trying to determine the impact of pipe heat gains on system performance and zone heat balance, particularly in comparing a DX system to a secondary system. Enter the value for suction piping heat gain (in W/C). That is, sum up the product of the pipe wall insulation conductance times the outer surface area of the pipe insulation. Please see the Engineering Reference for guidance in calculating this value. If the Sum UA Suction Piping is entered, the Suction Piping Zone Name is also required.

Field: Suction Piping Zone Name

This optional field is typically used when trying to determine the impact of pipe heat gains on system performance, particularly in comparing a DX system to a secondary system. (If the previous field, Sum UA Suction Piping, is blank, this field will not be used.) Enter the name of the zone where the suction piping is located. The suction piping heat gains will be calculated based upon the air temperature within this zone. The heat balance of this zone will also be affected by the piping heat exchange. Additional output variables are described at the end of this “Group-Refrigeration” section for the total impact of refrigeration on zones, including suction pipe heat exchange.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Number of Compressor Stages

This field determines whether the refrigeration system contains one or two stages of compression. In this field, enter either "1" for single-stage compression systems or "2" for two-stage compression systems. If two stages of compression are selected, then an intercooler will be used between the compressor stages to cool the discharge of the low-stage compressors. The default value is "1".

Field: Intercooler Type

This field determines the type of intercooler which is used for two-stage compression systems. Valid choices for this field include "None", "Flash Intercooler" or "Shell-and-Coil Intercooler". Single-stage systems require "None" while two-stage systems require either "Flash Intercooler" or "Shell-and-Coil Intercooler". The default selection is "None", corresponding to a single-stage compression system.

Field: Shell-and-Coil Intercooler Effectiveness

When a shell-and-coil intercooler is selected for two-stage compression systems, this field allows the specification of the shell-and-coil intercooler effectiveness. Values in this field will only be valid if "Shell-and-Coil Intercooler" is selected in the "Intercooler Type" field above. The valid range of values for this field is between 0.0 and 1.0. A default value of 0.80 will be used if none is specified.

Field: High-Stage Compressor or CompressorList Name

Identifies a single compressor, or a particular list of compressors, that comprise the high-stage compression of a two-stage compression refrigeration system. The name will be validated against the compressor list names (ref: List:Refrigeration:Compressors) in the input file. Names in this field are only valid if two compressor stages have been specified in the "Number of Compressor Stages" field above.

The following is an example input for a single-stage compression refrigeration system.

 HVAC,Average, Refrigeration Chiller System Liquid Temperature to TXV [C]

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE CASES AND/OR WALKINS***Refrigeration System Total Compressor Electric Power [W]***

This output is the total electric power input to the system compressor(s) in Watts.

Refrigeration System Total Compressor Electric Consumption [J]

This is the electricity consumption of the system's compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration System Total Low-Stage Compressor Electric Power [W]

This output is the total electric power input to the system's low-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

Refrigeration System Total Low-Stage Compressor Electric Consumption [J]

This is the electricity consumption of the system's low-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a

report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration System Total High-Stage Compressor Electric Power [W]

This output is the total electric power input to the system's high-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

Refrigeration System Total High-Stage Compressor Electric Consumption [J]

This is the electricity consumption of the system's high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration System Total Low- and High-Stage Compressor Electric Consumption [J]

This is the total electricity consumption of the system's low- and high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration System Average Compressor COP [W/W]

This output is the system average compressor COP, the total refrigeration effect divided by the total power to the compressors.

Refrigeration System Total Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the Refrigeration Compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value.

Refrigeration System Total Compressor Heat Transfer Energy [J]

This is the total heat transfer of the Refrigeration Compressor rack in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration System Total Low-Stage Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the low-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

Refrigeration System Total Low-Stage Compressor Heat Transfer Energy [J]

This is the total heat transfer of the low-stage compressors in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration System Total High-Stage Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the high-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

Refrigeration System Total High-Stage Compressor Heat Transfer Energy [J]

This is the total heat transfer of the high-stage compressors in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration System Total Cases and Walk-Ins Heat Transfer Rate [W]

This output is the total heat transfer rate from the refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

Refrigeration System Total Cases and Walk-Ins Heat Transfer Energy [J]

This output is the total heat transfer energy from the refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

Refrigeration System Total Transferred Load Heat Transfer Rate [W]

This output is the sum of the heat transfer rates for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing cooling to this system in Watts. Therefore, if the only transfer load between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

Refrigeration System Total Transferred Load Heat Transfer Energy [J]

This output is the sum of the heat transferred for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing cooling to this system in Joules. Therefore, if the only transfer load between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

Refrigeration System Total Suction Pipe Heat Gain Rate [W]

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

Refrigeration System Total Suction Pipe Heat Gain Energy [J]

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

Refrigeration System Net Heat Rejected Rate [W]

This output is the total heat rejected by this system to the system condenser in Watts. It does not include system heat rejection that has been recovered for useful purposes. However, if a

water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

Refrigeration System Net Heat Rejected Energy [J]

This output is the total heat rejected by this system to the system condenser in Joules for the timestep being reported. It does not include system heat rejection that has been recovered for useful purposes. However, if a water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

Refrigeration Liquid Suction Subcooler Load Transfer Rate [W]

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

Refrigeration Liquid Suction Subcooler Load Transfer Energy [J]

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

Refrigeration System Estimated Refrigerant Inventory [kg]

This output is the sum of the input inventory values for the condenser, receiver, cases, and liquid pipes that are a part of this system.

Refrigeration System Estimated Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow through the compressors for this system.

Refrigeration System Estimated Low-Stage Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow through the low-stage compressors for this system. This output is valid only for two-stage compression systems.

Refrigeration System Estimated High-Stage Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow through the high-stage compressors for this system. This output is valid only for two-stage compression systems.

Refrigeration System Intercooler Temperature [C]

This is the saturation temperature in the intercooler. This output is valid only for two-stage compression systems.

Refrigeration System Intercooler Pressure [Pa]

This is the saturation pressure in the intercooler. This output is valid only for two-stage compression systems.

Refrigeration System Condensing Temperature [C]

This is the saturated condensing temperature.

Refrigeration System Evaporating Temperature [C]

This is the saturated evaporating temperature.

Refrigeration System Suction Temperature [C]

This is the temperature at the compressor inlet including superheat after the cases and superheat from any liquid suction heat exchangers.

Refrigeration System Liquid Temperature to TXV [C]

This is the temperature entering the thermal expansion valve before the cases, equal to the condensing temperature minus any subcooling included in the condenser or provided by mechanical and/or liquid suction heat exchanger subcoolers.

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE AIR CHILLERS**Refrigeration Chiller System Total Compressor Electric Power [W]**

This output is the total electric power input to the system compressor(s) in Watts.

Refrigeration Chiller System Total Compressor Electric Consumption [J]

This is the electricity consumption of the system's compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller System Total Low-Stage Compressor Electric Power [W]

This output is the total electric power input to the system's low-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total Low-Stage Compressor Electric Consumption [J]

This is the electricity consumption of the system's low-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total High-Stage Compressor Electric Power [W]

This output is the total electric power input to the system's high-stage compressor(s) in Watts. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total High-Stage Compressor Electric Consumption [J]

This is the electricity consumption of the system's high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total Low- and High-Stage Compressor Electric Consumption [J]

This is the total electricity consumption of the system's low- and high-stage compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration Chiller System Average Compressor COP [W/W]

This output is the system average compressor COP, the total refrigeration effect divided by the total power to the compressors

Refrigeration Chiller System Total Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the Refrigeration Compressor rack in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value.

Refrigeration Chiller System Total Compressor Heat Transfer Energy [J]

This is the total heat transfer of the Refrigeration Compressor rack in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller System Total Low-Stage Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the low-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total Low-Stage Compressor Heat Transfer Energy [J]

This is the total heat transfer of the low-stage compressors in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total High-Stage Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the high-stage compressors in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases, walk-ins, secondary loops, cascade condensers, and mechanical subcoolers that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total High-Stage Compressor Heat Transfer Energy [J]

This is the total heat transfer of the high-stage compressors in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter). This output is valid only for two-stage compression systems.

Refrigeration Chiller System Total Air Chiller Heat Transfer Rate [W]

This output is the total heat transfer rate from the refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

Refrigeration Chiller System Total Cases and Walk-Ins Heat Transfer Energy [J]

This output is the total heat transfer energy from the refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the refrigerated cases and walk-ins that are connected directly to this system. This value does not include compressor or condenser fan heat or the heat transfer for cases and walk-ins served by any connected secondary systems.

Refrigeration Chiller System Total Transferred Load Heat Transfer Rate [W]

This output is the sum of the heat transfer rates for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing cooling to this system in Watts. Therefore, if the only transfer load between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

Refrigeration Chiller System Total Transferred Load Heat Transfer Energy [J]

This output is the sum of the heat transferred for any secondary loops, cascade condensers, and mechanical subcoolers cooled by this system, minus the benefit of any mechanical subcooler providing cooling to this system in Joules. Therefore, if the only transfer load

between two systems is a mechanical subcooler, the same amount will show as a negative value for the system receiving the cooling effect and as a positive number for the system serving that cooling load. It also includes the pump energy for any secondary loops and the compressor energy for any cascade condenser systems that are cooled by this system. (See the Engineering Reference for more details about the loads placed by secondary systems upon the primary system.)

Refrigeration Chiller System Total Suction Pipe Heat Gain Rate [W]

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

Refrigeration Chiller System Total Suction Pipe Heat Gain Energy [J]

This output is the total heat transfer rate for suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the suction piping heat gain characteristics in the input.

Refrigeration Chiller System Net Heat Rejected Rate [W]

This output is the total heat rejected by this system to the system condenser in Watts. It does not include system heat rejection that has been recovered for useful purposes. However, if a water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

Refrigeration Chiller System Net Heat Rejected Energy [J]

This output is the total heat rejected by this system to the system condenser in Joules for the timestep being reported. It does not include system heat rejection that has been recovered for useful purposes. However, if a water-cooled condenser was used to provide heat to a separate water loop, the energy transferred to that loop is included here.

Refrigeration Liquid Suction Subcooler Load Transfer Rate [W]

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

Refrigeration Liquid Suction Subcooler Load Transfer Energy [J]

This output is the total heat transferred from the liquid condensate before the thermal expansion valve to the suction gas.

Refrigeration Chiller System Estimated Refrigerant Inventory [kg]

This output is the sum of the input inventory values for the condenser, receiver, cases, and liquid pipes that are a part of this system.

Refrigeration Chiller System Estimated Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow through the compressors for this system.

Refrigeration Chiller System Estimated Low-Stage Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow through the low-stage compressors for this system. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Estimated High-Stage Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow through the high-stage compressors for this system. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Intercooler Temperature [C]

This is the saturation temperature in the intercooler. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Intercooler Pressure [Pa]

This is the saturation pressure in the intercooler. This output is valid only for two-stage compression systems.

Refrigeration Chiller System Condensing Temperature [C]

This is the saturated condensing temperature.

Refrigeration Chiller System Evaporating Temperature [C]

This is the saturated evaporating temperature.

Refrigeration Chiller System Suction Temperature [C]

This is the temperature at the compressor inlet including superheat after the cases and superheat from any liquid suction heat exchangers.

Refrigeration Chiller System Liquid Temperature to TXV [C]

This is the temperature entering the thermal expansion valve before the cases, equal to the condensing temperature minus any subcooling included in the condenser or provided by mechanical and/or liquid suction heat exchangers.

Refrigeration:TranscriticalSystem

The Refrigeration:TranscriticalSystem object allows users to model detailed transcritical carbon dioxide (CO₂) booster refrigeration systems used in supermarkets. The object allows for modeling either a single stage system with medium-temperature loads or a two stage system with both medium- and low-temperature loads.

The input objects required to model a detailed transcritical CO₂ refrigeration system include the following:

- One Refrigeration:TranscriticalSystem object,
- At least one refrigeration load object which may include any combination of the following:
 - Refrigeration:Case,
 - Refrigeration:WalkIn,
 - Refrigeration:CaseAndWalkInList (may include both cases and/or walk-in cooler names),
- At least one Refrigeration:Compressor object (multiple compressors are entered using a Refrigeration:CompressorList),
- One Refrigeration:GasCooler:AirCooled object,

Output variables are available to describe the total heat exchange between all the refrigeration objects and the zones containing these objects. These variables are described at the end of this section.

At least one refrigeration load object must be defined which may be one of two types of loads, including a refrigerated display case and a walk-in cooler, (Ref. Refrigeration:Case, and Refrigeration:WalkIn). If multiple loads are served by the same system, the user should use the refrigerated case and walk-in list object available to assign all cases and walk-ins cooled directly by this system (Ref. Refrigeration:CaseAndWalkInList).

The name of at least one compressor must be defined and a list object is available if the system is served by more than one compressor (Ref. Refrigeration:Compressor and Refrigeration:CompressorList).

Heat is rejected to the outdoors via an air-cooled gas cooler (Ref. Refrigeration:GasCooler:AirCooled).

The Refrigeration:TranscriticalSystem object coordinates the energy flows between the other refrigeration objects and is used to set system parameters.

The inputs for the refrigeration system object, in addition to the names of the other refrigeration objects described above, include a name for this system, the receiver pressure, the subcooler effectiveness, and the refrigeration system working fluid. Optional input fields are also provided for users seeking to keep track of suction pipe heat gains.

A detailed description of the transcritical CO₂ booster refrigeration system may be found in the Refrigeration section of the Engineering Reference.

Field: Name

A unique user-assigned name for an instance of a transcritical CO₂ refrigeration system. Any reference to this refrigeration system by another object will use this name.

Field: System Type

Identifies the transcritical CO₂ refrigeration system as either a single-stage system with only medium-temperature loads, or a two-stage system with both medium- and low-temperature loads. Valid choices are: SingleStage for single stage systems or TwoStage for two stage systems.

Field: Medium Temperature Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, a single walk-in, or a particular list of refrigerated cases and walk-ins, that is cooled by the medium-temperature stage of the refrigeration system. The name will be validated against the case, walk-in, and CaseAndWalkInList names (Ref. Refrigeration:Case, Refrigeration:WalkIn, and Refrigeration:CaseAndWalkInList) in the input file. Only medium temperature cases and walk-ins served directly by the system should be included in this list. Note that this entry is required for both single-stage and two-stage systems.

Field: Low Temperature Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, a single walk-in, or a particular list of refrigerated cases and walk-ins, that is cooled by the low-temperature stage of the refrigeration system. The name will be validated against the case, walk-in, and CaseAndWalkInList names (Ref. Refrigeration:Case, Refrigeration:WalkIn, and Refrigeration:CaseAndWalkInList) in the input file. Only low temperature cases and walk-ins served directly by the system should be included in this list. Note that this entry is valid only for two-stage systems.

Field: Refrigeration Gas Cooler Name

The name of the gas cooler that is used to reject heat from the transcritical refrigeration system. The name will be validated against the gas cooler names (Ref. Refrigeration:GasCooler:AirCooled) in the input file.

Field: High Pressure Compressor or Compressor List Name

Identifies a single compressor, or a particular list of compressors, that provides compression for a single-stage system or the high pressure stage of a two-stage system. The name will be validated against the compressor list names (Ref. List:Refrigeration:Compressors) in the input file. Note that this entry is required for both single-stage and two-stage systems.

Field: Low Pressure Compressor or Compressor List Name

Identifies a single compressor, or a particular list of compressors, that provides compression for the low pressure stage of a two-stage system. The name will be validated against the compressor list names (Ref. List:Refrigeration:Compressors) in the input file. Note that this entry is valid only for two-stage systems.

Field: Receiver Pressure

This numeric field specifies the refrigerant pressure (Pa) in the receiver. The default value for the receiver pressure is 4.0×10^6 Pa.

Field: Subcooler Effectiveness

This numeric field specifies the heat exchanger effectiveness of the subcooler. The default value for the subcooler effectiveness is 0.4.

Field: Refrigeration System Working Fluid Type

The type of refrigerant used by the system. It is assumed that carbon dioxide will be the refrigerant used in the transcritical CO₂ refrigeration system. However, the user must specify the name used in the input file which refers to carbon dioxide. This name will be validated against Fluid Names (Ref. Fluid Properties section) in the input file. Note that the corresponding property data for carbon dioxide (R744), available in FluidPropertiesRefData.idf, must be supplied in the input file.

Field: Sum UA Suction Piping for Medium Temperature Loads

This optional field is typically used to determine the impact of pipe heat gains on system performance and zone heat balance. Enter the value for suction piping heat gain (in W/C) for the medium-temperature suction line, i.e., sum up the product of the pipe wall insulation conductance times the outer surface area of the pipe insulation. Please see the Engineering Reference for guidance in calculating this value. If the Sum UA Suction Piping for Medium Temperature Loads is entered, the Medium Temperature Suction Piping Zone Name is also required.

Field: Medium Temperature Suction Piping Zone Name

This optional field is typically used to determine the impact of pipe heat gains on system performance. If the previous field, Sum UA Suction Piping for Medium Temperature Loads, is blank, this field will not be used. Enter the name of the zone where the medium-temperature suction piping is located. The suction piping heat gains will be calculated based upon the air temperature within this zone. The heat balance of this zone will also be affected by the piping heat exchange. Additional output variables are described at the end of this section for the total impact of refrigeration on zones, including suction pipe heat exchange.

Field: Sum UA Suction Piping for Low Temperature Loads

This optional field is typically used to determine the impact of pipe heat gains on system performance and zone heat balance. Enter the value for suction piping heat gain (in W/C) for the low-temperature suction line, i.e., sum up the product of the pipe wall insulation conductance times the outer surface area of the pipe insulation. Please see the Engineering Reference for guidance in calculating this value. If the Sum UA Suction Piping for Low Temperature Loads is entered, the Low Temperature Suction Piping Zone Name is also required. Note that this entry is valid only for two-stage systems.

Field: Low Temperature Suction Piping Zone Name

This optional field is typically used to determine the impact of pipe heat gains on system performance. If the previous field, Sum UA Suction Piping for Low Temperature Loads, is blank, this field will not be used. Enter the name of the zone where the low-temperature suction piping is located. The suction piping heat gains will be calculated based upon the air temperature within this zone. The heat balance of this zone will also be affected by the piping heat exchange. Additional output variables are described at the end of this section for the total impact of refrigeration on zones, including suction pipe heat exchange. Note that this entry is valid only for two-stage systems.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Medium Temperature System"). A new meter for reporting is created for each unique subcategory (Ref. Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

The following is an example input for a transcritical CO₂ refrigeration system.

Transcritical Refrigeration System Total High Pressure Compressor Electric Power [W]

This output is the total electric power input to the system's high pressure compressor(s) in Watts.

Transcritical Refrigeration System Total High Pressure Compressor Electric Consumption [J]

This is the electricity consumption of the system's high pressure compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Transcritical Refrigeration System Total Low Pressure Compressor Electric Power [W]

This output is the total electric power input to the system's low pressure compressor(s) in Watts.

Transcritical Refrigeration System Total Low Pressure Compressor Electric Consumption [J]

This is the electricity consumption of the system's low pressure compressor(s) in Joules for the timestep being reported. The individual consumption for each compressor is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Transcritical Refrigeration System Total Compressor Electric Consumption [J]

This output is the total electric power input to all of the system's compressor(s) in Watts.

Transcritical Refrigeration System Average COP [W/W]

This output is the system average compressor COP, which is the total refrigeration effect divided by the total power to all of the compressors.

Transcritical Refrigeration System Total Medium Temperature Cases and Walk-Ins Heat Transfer Rate [W]

This output is the total heat transfer rate from the medium temperature refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates for the medium temperature refrigerated cases and walk-ins that are connected directly to this system.

Transcritical Refrigeration System Total Medium Temperature Cases and Walk-Ins Heat Transfer Energy [J]

This output is the total heat transfer energy from the medium temperature refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the medium temperature refrigerated cases and walk-ins that are connected directly to this system.

Transcritical Refrigeration System Total Low Temperature Cases and Walk-Ins Heat Transfer Rate [W]

This output is the total heat transfer rate from the low temperature refrigerated cases and walk-ins served directly by this system in Watts. It is the sum of all of the heat transfer rates

for the low temperature refrigerated cases and walk-ins that are connected directly to this system.

Transcritical Refrigeration System Total Low Temperature Cases and Walk-Ins Heat Transfer Energy [J]

This output is the total heat transfer energy from the low temperature refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for the low temperature refrigerated cases and walk-ins that are connected directly to this system.

Transcritical Refrigeration System Total Cases and Walk-Ins Heat Transfer Energy [J]

This output is the total heat transfer energy from all the low- and medium-temperature refrigerated cases and walk-ins served directly by this system in Joules. It is the sum of all of the heat transferred for all the refrigerated cases and walk-ins that are connected directly to this system.

Transcritical Refrigeration System Total Medium Temperature Suction Pipe Heat Gain Rate [W]

This output is the total heat transfer rate for the medium-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the medium-temperature suction piping heat gain characteristics in the input.

Transcritical Refrigeration System Total Medium Temperature Suction Pipe Heat Gain Energy [J]

This output is the total heat transfer rate for the medium-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the medium-temperature suction piping heat gain characteristics in the input.

Transcritical Refrigeration System Total Low Temperature Suction Pipe Heat Gain Rate [W]

This output is the total heat transfer rate for the low-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the low-temperature suction piping heat gain characteristics in the input.

Transcritical Refrigeration System Total Low Temperature Suction Pipe Heat Gain Energy [J]

This output is the total heat transfer rate for the low-temperature suction piping served by this system in Watts. Note this is an optional input, and is only available if the user has described the low-temperature suction piping heat gain characteristics in the input.

Transcritical Refrigeration System Total High Pressure Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the high pressure Compressors in Watts. It is the sum of all of the heat transfer rates for the low- and medium-temperature refrigerated cases and walk-ins as well as the low pressure compressors that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value.

Transcritical Refrigeration System Total High Pressure Compressor Heat Transfer Energy [J]

This is the total heat transfer of the high pressure compressors in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Transcritical Refrigeration System Total Low Pressure Compressor Heat Transfer Rate [W]

This output is the total heat transfer rate of the low pressure Compressors in Watts. It is the sum of all of the heat transfer rates for the low temperature refrigerated cases and walk-ins that are cooled by this system. This value does not include compressor or condenser fan heat. If specified as an input value, the suction pipe heat gains are included in this value.

Transcritical Refrigeration System Total Low Pressure Compressor Heat Transfer Energy [J]

This is the total heat transfer of the low pressure compressors in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Transcritical Refrigeration System Net Heat Rejected Rate [W]

This output is the total heat rejected by this system to the system gas cooler in Watts. It does not include system heat rejection that has been recovered for useful purposes.

Transcritical Refrigeration System Net Heat Rejected Energy [J]

This output is the total heat rejected by this system to the system gas cooler in Joules for the timestep being reported. It does not include system heat rejection that has been recovered for useful purposes.

Transcritical Refrigeration System Refrigerant Inventory [kg]

This output is the sum of the input refrigerant inventory values for the gas cooler, receiver, cases, and liquid pipes that are a part of this system.

Transcritical Refrigeration System Total Refrigerant Mass Flow [kg/s]

This output is the calculated refrigerant mass flow rate through the high pressure compressors for this system.

Transcritical Refrigeration System Medium Temperature Evaporating Temperature [C]

This is the saturated evaporating temperature for the medium temperature loads.

Transcritical Refrigeration System Medium Temperature Suction Temperature [C]

This is the temperature at the high pressure compressor inlet including superheat after the display cases and superheat from the suction line heat exchanger.

Transcritical Refrigeration System Low Temperature Evaporating Temperature [C]

This is the saturated evaporating temperature for the low-temperature loads.

Transcritical Refrigeration System Low Temperature Suction Temperature [C]

This is the temperature at the low pressure compressor inlet including superheat after the display cases.

Refrigeration:Compressor

The compressors are described here using manufacturer's data for curves that provide the efficiency, cooling capacity, and power consumption. The corresponding rated values for cycle superheat and subcooling are also required.

A dataset has been provided containing the compressor rating data, including the performance curve inputs, for a large number of compressors. See [RefrigerationCompressorCurves.idf](#).

Field: Name

A unique user-assigned name for an instance of a compressor. Any reference to this compressor by another object will use this name.

Field: Refrigeration Compressor Power Curve Name

This required field provides the name of the curve object that describes the compressor power as a function of the evaporating and condensing temperatures, as specified in ARI 540. The curve is of the bicubic form(ref: Curve:Bicubic). However, the input order for the Energy Plus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.

N3 is ARI C4 and N4 is ARI C3.

N5 is ARI C6 and N6 is ARI C5,

N7 is ARI C7.

N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.

N11 is the Minimum evaporating temperature and N12 is the Maximum evaporating temperature.

N13 is the the Minimum condensing temperature and N14 is the Maximum condensing temperature

Field: Refrigeration Compressor Capacity Curve Name

This required field provides the name of the curve object that describes the compressor cooling capacity as a function of the evaporating and condensing temperatures, as specified in ARI 540. The curve is of the bicubic form(ref: Curve:Bicubic). However, the input order for the Energy Plus bicubic curve does not match the ARI 540 standard order. When this curve is entered, the user should use the following assignments:

N1 is ARI C1 and N2 is ARI C2.

N3 is ARI C4 and N4 is ARI C3.

N5 is ARI C6 and N6 is ARI C5,

N7 is ARI C7.

N8 is ARI C10, N9 is ARI C8, and N10 is ARI C9.

N11 is the Minimum evaporating temperature and N12 is Maximum evaporating temperature.

N13 is the Minimum condensing temperature and N14 is the Maximum condensing temperature

Field: Rated Superheat

Some manufacturers specify a constant return gas temperature while others specify a constant superheat (the difference between the saturated evaporating temperature and the actual return gas temperature). Use this field for compressors that provide their rated superheat. (Do NOT use both this field and the Rated Return Gas Temperature field.) The rated superheat is specified in units of delta C.

Field: Rated Return Gas Temperature

Some manufacturers specify a constant return gas temperature (which may also be called the Rated Suction Temperature) while others specify a constant superheat. Use this field for compressors that provide their rated return gas temperature. (Do NOT use both this field and the Rated Superheat field.) The rated return gas temperature is specified in units of C.

Field: Rated Liquid Temperature

Some compressor manufactures rate their equipment according to a constant subcooling (the difference between the saturated condensing temperature and the actual liquid temperature entering the thermal expansion valve before the refrigeration load). Other manufacturers specify a constant liquid temperature.Use this field if the manufacturer specifies the rated liquid temperature. (Do NOT use both this field and the Rated Subcooling field.) The units for this field are degrees C.

Field: Rated Subcooling

Some compressor manufacturers rate their equipment according to a constant subcooling (the difference between the saturated condensing temperature and the actual liquid temperature entering the thermal expansion valve before the refrigeration load). Other manufacturers specify a constant liquid temperature. Use this field if the manufacturer specifies the rated subcooling. (Do NOT use both this field and the Rated Liquid Temperature field.) The units for this field are delta C.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature System"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

The following is an example input for a refrigeration compressor.

```
Refrigeration:Compressor,
  CompressorA,           ! - Name
  PowerCurveCompA,       ! - Refrigeration Compressor Power Curve Name
  CapCurveCompA,         ! - Refrigeration Compressor Capacity Curve Name

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE CASES AND/OR WALKINS

Refrigeration Compressor Electric Power [W]

This output is the electric power input to the compressor in Watts.

Refrigeration Compressor Electric Energy [J]

This is the electric energy consumed by the compressor in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Compressor Heat Transfer Rate [W]

This output is the heat removed from the refrigerated cases by the compressor in Watts.

Refrigeration Compressor Heat Transfer Energy [J]

This is the heat removed from the refrigerated cases by the compressor in Joules for the timestep being reported.

Refrigeration Compressor Run Time Fraction []

This is the fraction of the time step when the compressor ran to meet the load. It is a value between 0.0 and 1.0.

THE FOLLOWING OUTPUTS ARE AVAILABLE FOR SYSTEMS THAT SERVE AIR CHILLERS

Refrigeration Chiller Compressor Electric Power [W]

This output is the electric power input to the compressor in Watts.

Refrigeration Chiller Compressor Electric Energy [J]

This is the electric energy consumed by the compressor in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller Compressor Heat Transfer Rate [W]

This output is the heat removed from the refrigerated cases by the compressor in Watts.

Refrigeration Chiller Compressor Heat Transfer Energy [J]

This is the heat removed from the refrigerated cases by the compressor in Joules for the timestep being reported.

Refrigeration Chiller Compressor Run Time Fraction []

This is the fraction of the time step when the compressor ran to meet the load. It is a value between 0.0 and 1.0.

Refrigeration:CompressorList

This object provides a list of all the compressors included within a single refrigeration system (Ref: Refrigeration:System). Each list must contain at least one compressor. The order in which the individual compressors are listed here will be the order in which the compressors are dispatched to meet the system load. That is, at very low loads, only compressor #1 will be operating. As the load increases, the first two compressors will be operating, and so on. This list is extensible.

Field: Name

A unique user-assigned name for an instance of a compressor list. Any reference to this compressor list by another object will use this name. The compressor list cannot have the same name as any individual compressor.

Field: Refrigeration Compressor <x> Name

Identifies a particular compressor that works in conjunction with the other compressors on this list to provide cooling to a single refrigeration system. The name will be validated against the compressor names (ref: Refrigeration:Compressor) in the input file. Up to 20 are available in the IDD; this object is extensible.

The following is an example input for a compressor list.

```
Refrigeration:CompressorList,
  MediumTempCompressorlist, !- Refrigeration Compressor List Name
  CompressorA,           !- Refrigeration Compressor Name #1
  CompressorB,           !- Refrigeration Compressor Name #2
  CompressorC;          !- Refrigeration Compressor Name #3
```

Refrigeration:Subcooler

Two types of subcoolers are modeled by the detailed refrigeration system. As described in the Engineering Reference, the liquid suction heat exchanger uses cool suction gas to

subcool the hot condensate after it leaves the condenser and before it reaches the thermal expansion valve. For the liquid suction heat exchanger, both the source and sink of energy are located within the same refrigeration system. In contrast, a mechanical subcooler is used to transfer cooling capacity from one refrigeration system to another. The mechanical subcooler is listed as a part of the system for which the condensate is cooled. However, the input data for the mechanical subcooler includes a field that identifies the system that provides the cooling capacity.

Field: Name

A unique user-assigned name for an instance of a subcooler. Any reference to this subcooler by another object will use this name.

Field: Subcooler Type

The type of subcooler. Valid choices are Mechanical and LiquidSuction. If the field is blank, the default will be LiquidSuction.

Field: Liquid Suction Design Subcooling Temperature Difference

This numeric field is the design subcooling temperature difference (DeltaC) for a liquid suction heat exchanger and should be blank for a mechanical subcooler.

Field: Design Liquid Inlet Temperature

This numeric field is the design inlet temperature (C) for the hot liquid entering a liquid suction heat exchanger and should be blank for a mechanical subcooler.

Field: Design Vapor Inlet Temperature

This numeric field is the design inlet temperature (C) for the cool vapor entering a liquid suction heat exchanger and should be blank for a mechanical subcooler.

Field: Capacity-Providing System

This field is the name of the refrigeration system object that provides the cooling capacity for the mechanical subcooler (ref: Refrigeration:System Name). This field should be blank for a liquid suction heat exchanger.

Field: Outlet Control Temperature

This numeric field is the controlled outlet temperature (C) for subcooled liquid exiting a mechanical subcooler. This field should be blank for a liquid suction heat exchanger.

The following is example input for both liquid suction and mechanical subcoolers.

```

Refrigeration Mechanical Subcooler Load Transfer Energy [J]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Joules.

FOR SUBCOOLERS ON SYSTEMS SERVING AIR CHILLERS

Refrigeration Mechanical Subcooler Load Transfer Rate [W]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Watts.

Refrigeration Mechanical Subcooler Load Transfer Energy [J]

This output is the cooling energy transferred from one system's compressor group to the refrigerant leaving the condenser for another refrigeration system in Joules.

Refrigeration:Condenser:AirCooled

The refrigeration system requires a single condenser to reject the system heat. The air cooled condenser object is one of four options for this condenser. In an air-cooled condenser, the total heat of rejection is characterized by a linear relationship between the difference between the inlet air (usually the outside drybulb) and condensing temperatures. This curve is commonly found in the condenser manufacturers' literature. This rating curve, which corresponds to ARI 460 standards, also has an associated rated value for subcooling that should be entered. The rated condenser fan power and fan speed control type must be specified. If the condenser is not at ground level, the user may specify an air inlet node name (ref: OutdoorAir:Node name). If the condenser is located inside a conditioned zone, the zone name may be specified(ref: bbbZoneNamebbb). Optional input is provided to help the user

compare refrigerant inventories for different systems. These inputs represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Field: Name

Identifies a particular condenser that rejects heat for a one or more refrigeration system(s). The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser:*) in the input file, including names used for evaporative-cooled, water-cooled, and cascade-cooled condensers.

Field: Rated Effective Total Heat Rejection Rate Curve Name

This field is the name of a curve object defining the condenser heat rejection as a function of the difference between the condensing and entering air temperatures. The curve should be linear (Curve:Linear). See the Engineering Reference for more discussion on the curve coefficients.

Field: Rated Subcooling Temperature Difference

This numeric field specifies the rated subcooling (DeltaC) specified by the manufacturer, consistent with the heat rejection curve rating data.

Field: Condenser Fan Speed Control Type

The type of fan speed control used by the condenser fan. Valid choices are **Fixed**, **FixedLinear**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

Field: Rated Fan Power

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions.

Field: Minimum Fan Air Flow Ratio

Fan controls often include a minimum air flow ratio to avoid overheating the fan motor or for other reasons. This numeric field should be between 0. and 1. and has a default value of 0.2.

Field: Air Inlet Node Name or Zone Name

This optional alpha field contains the name of the node from which the condenser draws its outdoor air or the name of the conditioned zone where the condenser is located. If this field is left blank, the outdoor air drybulb temperature entering the condenser is taken directly from the weather data. If this field is not blank and an outdoor air node name is entered, this node name must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If a zone name is entered,bbb

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

The following is an example input for an air-cooled condenser.

FOR CONDENSERS ON SYSTEMS SERVING CASES AND/OR WALKINS:

Refrigeration System Condenser Fan Electric Power [W]

This output is the electric input to the system's condenser fan(s) in Watts.

Refrigeration System Condenser Fan Electric Consumption [J]

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

Refrigeration System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

Refrigeration System Condenser Total Recovered Heat Rate [W]

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating.

Refrigeration System Condenser Total Recovered Heat Energy [J]

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating for the timestep being reported.

Refrigeration System Condenser Heat Recovered for Non-Refrigeration Purposes Rate [W]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

Refrigeration System Condenser Heat Recovered for Non-Refrigeration Purposes Energy [J]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

Refrigeration System Condenser Heat Recovered for Refrigeration Defrost Rate [W]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system.

Refrigeration System Condenser Heat Recovered for Refrigeration Defrost Energy [J]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:***Refrigeration Chiller System Condenser Fan Electric Power [W]***

This output is the electric input to the system's condenser fan(s) in Watts.

Refrigeration Chiller System Condenser Fan Electric Consumption [J]

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

Refrigeration Chiller System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported (i.e., compressor energy and refrigeration load minus any heat recovered for defrost or other purposes).

Refrigeration Chiller System Condenser Total Recovered Heat Rate [W]

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating.

Refrigeration Chiller System Condenser Total Recovered Heat Energy [J]

This is the total heat recovered from the condenser inlet flow for all purposes including defrost and water or air heating for the timestep being reported.

Refrigeration Chiller System Condenser Heat Recovered for Non-Refrigeration Purposes Rate [W]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

Refrigeration Chiller System Condenser Heat Recovered for Non-Refrigeration Purposes Energy [J]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

Refrigeration Chiller System Condenser Heat Recovered for Refrigeration Defrost Rate [W]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system.

Refrigeration Chiller System Condenser Heat Recovered for Refrigeration Defrost Energy [J]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

Refrigeration:Condenser:EvaporativeCooled

Each refrigeration system requires a single condenser. The evaporative cooled condenser object is one of four options for this condenser. In an evaporative-cooled condenser, the total heat of rejection is characterized by a four-factor relationship between the condensing temperature and the difference between the outside wetbulb and condensing temperatures. This curve must be developed by regression from the condenser manufacturers' literature. This rating curve, which is based upon rated data taken according to ARI 460 standards, also has an associated rated value for subcooling that should be entered. The rated condenser fan power and fan speed control type must be specified. If the condenser is not at ground level, the user may specify an air inlet node name (ref: OutdoorAir:Node name). Optional input is provided to help the user compare refrigerant inventories for different systems. These input represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Additional inputs are needed for basin heater parameters, water pump power, and water source. An evaporative cooling availability schedule is available.

Field: Name

Identifies a particular condenser that rejects heat for a one or more refrigeration system(s). The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser:*) in the input file, including names used for air-cooled, water-cooled and cascade-cooled condensers.

Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W) at standard rating conditions per ARI 490. Be sure the rating corresponds to the correct refrigerant.

Field: Rated Subcooling Temperature Difference

This numeric field specifies the rated subcooling (DeltaC) specified by the manufacturer, consistent with the rated value for total heat rejection.

Field: Fan Speed Control Type

The type of fan speed control used by the condenser fan. Valid choices are **Fixed**, **FixedLinear**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

Field: Rated Fan Power

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions.

Field: Minimum Fan Air Flow Ratio

Fan controls often include a minimum air flow ratio to avoid overheating the fan motor or for other reasons. This numeric field has a minimum value of 0. and a default value of 0.2.

Field: Approach Temperature Constant Term

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$T_{\text{condense}} = A_1 + A_2(hrcf) + A_3/(hrcf) + (1 + A_4)(T_{\text{wb}})$$

This numeric field is the value for A1 and has a default value of 6.63, a minimum of 0. and a maximum of 20. (C)

Field: Approach Temperature Coefficient 2

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$T_{\text{condense}} = A_1 + A_2(hrcf) + A_3/(hrcf) + (1 + A_4)(T_{\text{wb}})$$

This numeric field is the value for A2 and has a default value of 0.468, a minimum of 0, and a maximum of 20 (C).

Field: Approach Temperature Coefficient 3

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$T_{\text{condense}} = A_1 + A_2(hrcf) + A_3/(hrcf) + (1 + A_4)(T_{\text{wb}})$$

This numeric field is the value for A3 and has a default value of 17.93, a minimum of 0, and a maximum of 30 (C).

Field: Approach Temperature Coefficient 4

As described in the Engineering Reference (ref Refrigeration:Condenser:Evaporative), the heat rejection capacity factor is specified according to the form (where Twetbulb and Tcondense are in C):

$$T_{\text{condense}} = A_1 + A_2(hrcf) + A_3/(hrcf) + (1 + A_4)(T_{\text{wb}})$$

This numeric field is the value for A4 and has a default value of -0.322, a minimum of -20., and a maximum of 20 (dimensionless).

Field: Minimum Capacity Factor

This numeric field is the minimum heat rejection capacity factor in the manufacturer's data used to develop the equation described in the preceding four fields. The default value is 0.5.

Field: Maximum Capacity Factor

This numeric field is the maximum heat rejection capacity factor in the manufacturer's data used to develop the equation described in the preceding four fields. The default value is 5.0.

Field: Air Inlet Node Name

This optional alpha field contains the name of the node from which the condenser draws its outdoor air. If this field is left blank, the outdoor air drybulb temperature entering the condenser is taken directly from the weather data. If this field is not blank, this node name must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Rated Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser. This value is used to calculate the amount of water evaporated when evaporatively cooling the condenser inlet air. The value for this field must be greater than zero. This input field is also autocalculatable, equivalent to $0.000144 \text{ m}^3/\text{s}$ per watt of total cooling capacity [850 cfm/ton] where the total cooling capacity is the total heat of rejection.

Field: Basin Heater Capacity

This field defines the power level of the basin heater, if applicable, used to avoid water freezing in an outdoor evaporative cooler basin. This numeric field contains the capacity of the electric basin heater in Watts per degree C. This field is used in conjunction with the Basin Heater Set Point Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the dry-bulb temperature of the condenser coil inlet air. The basin heater only operates when the condenser fan is off (i.e., no compressor heat rejection). The basin heater capacity must be greater than or equal to zero, with a default value of 200 W/C if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature ($^{\circ}\text{C}$) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this set point temperature, as long as the condenser fan is off. The default value is 2°C if this field is left blank.

Field: Rated Water Pump Power

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The value for this field must be greater than or equal to 0, with a default value of 1000 Watts if this field is left blank. This input field is also autocalculatable, equivalent to $0.004266 \text{ W per Watt}$ [15 W/ton] of total cooling capacity.

Field: Evaporative Water Supply Tank Name

This field is used to define where the condenser obtains water used for evaporative cooling. If this field is left blank, the unit will obtain water directly from the mains (Ref. Water Mains Temperatures). If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank.

Field: Evaporative Condenser Availability Schedule Name

For evaporative cooled condensers, the name of the optional schedule (Ref: Schedule) that specifies the time periods that evaporative cooling is available/unavailable. In some colder climates, evaporative cooling is periodically discontinued and the basin sumps drained to avoid freezing and to avoid ice formation on the condenser. In these times, the condenser

runs as a typical dry air cooled condenser, and related evaporative cooling systems (e.g., water pump, basin heaters) do not operate. Use of this optional schedule permits modeling of planned, seasonal interruptions of evaporative cooling. All schedule values must be greater than or equal to zero. Typically, an ON/OFF schedule type is used with values being either 0 or 1. A schedule value of 1 indicates that evaporative cooling is available during the defined time period, and a value of 0 denotes that evaporative cooling is not available during the defined time period. If the schedule name is omitted (blank), then the model assumes that evaporative cooling of the condenser is available for the entire simulation period. Note: the use of this schedule is the correct way to model an evaporative condenser in a climate subject to freezing weather. However, because some users will take a single model description and run it for a multiple climates, the code also includes an automatic switch from wet to dry operation, as described in the Engineering Reference.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

This is the total heat recovered from the condenser refrigerant inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

Refrigeration System Condenser Pump Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the condenser.

Refrigeration System Condenser Pump Electric Consumption [J]

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration System Condenser Basin Heater Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the condenser.

Refrigeration System Condenser Basin Heater Electric Consumption [J]

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration System Condenser Water Consumption Rate [m^3/s]

The volumetric flow rate in m^3/s of water consumed while providing evaporative cooling of the condenser.

Refrigeration System Condenser Water Consumption [m^3]

This is the water consumed by evaporation in m^3 while providing evaporative cooling of the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:**Refrigeration Chiller System Condenser Fan Electric Power [W]**

This output is the electric input to the system's condenser fan(s) in Watts.

Refrigeration Chiller System Condenser Fan Electric Consumption [J]

This is the electricity consumption of the system's condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

Refrigeration Chiller System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

Refrigeration Chiller System Condenser Total Recovered Heat Rate [W]

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose.

Refrigeration Chiller System Condenser Total Recovered Heat Energy [J]

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose for the timestep being reported.

Refrigeration Chiller System Condenser Heat Recovered for Non-Refrigeration Purposes Rate [W]

This is the total heat recovered from the condenser refrigerant inlet flow for purposes such as water or air heating.

Refrigeration Chiller System Condenser Heat Recovered for Non-Refrigeration Purposes Energy [J]

This is the total heat recovered from the condenser refrigerant inlet flow for purposes such as water or air heating for the timestep being reported.

Refrigeration Chiller System Condenser Heat Recovered for Refrigeration Defrost Rate [W]

This is the total heat recovered from the condenser refrigerant inlet flow for defrost purposes within the refrigeration system.

Refrigeration Chiller System Condenser Heat Recovered for Refrigeration Defrost Energy [J]

This is the total heat recovered from the condenser refrigerant inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

Refrigeration Chiller System Condenser Pump Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water pump used with evaporative cooling of the condenser.

Refrigeration Chiller System Condenser Pump Electric Consumption [J]

This is the electricity consumption in Joules of the water pump used with evaporative cooling of the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration Chiller System Condenser Basin Heater Electric Power [W]

This is the electrical power requirement in Watts for the timestep being reported for the water heater in the basin of the evaporative system used to cool the condenser.

Refrigeration Chiller System Condenser Basin Heater Electric Consumption [J]

This is the electricity consumption in Joules of the water heater used to prevent freezing of the evaporative cooling system for the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration Chiller System Condenser Water Consumption Rate [m^3/s]

The volumetric flow rate in m^3/s of water consumed while providing evaporative cooling of the condenser.

Refrigeration Chiller System Condenser Water Consumption [m^3]

This is the water consumed by evaporation in m^3 while providing evaporative cooling of the condenser for the timestep being reported. This output is also added to a report meter with Resource Type = Water, End Use Key = Refrigeration, Group Key = Plant. Use of an optional subkey category is also available, with default to the General end-use subcategory (Ref. Report Meter).

Refrigeration:Condenser:WaterCooled

The refrigeration system requires a single condenser. The water cooled condenser object is one of four options for this condenser. Manufacturer's data is required for the rated total heat rejection, the rated condensing temperature, and the rated leaving liquid refrigerant temperature, all per ARI 450. These values are used to calculate the subcooling included in the rated capacity. The inlet and outlet node names as well as the water outlet temperature schedule name are required. Optional input is provided to help the user compare refrigerant inventories for different systems. These input represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Field: Name

Identifies a particular condenser that rejects heat for one or more refrigeration system(s). The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser) in the input file, including names used for air-cooled, evaporative-cooled, and cascade-cooled condensers.

Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W) at standard rating conditions per ARI 450. Be sure the rating corresponds to the correct refrigerant.

Field: Rated Condensing Temperature

This numeric field provides the rated condensing temperature (C) corresponding to the rated heat rejection capacity.

Field: Rated Subcooling Temperature Difference

This numeric field provides the rated liquid refrigerant subcooling (DeltaC) corresponding to the rated heat rejection capacity. Note this is equal to the difference between the saturated condensing temperature and the leaving liquid refrigerant temperature.

Field: Rated Water Inlet Temperature

This numeric field provides the rated water inlet temperature (C) corresponding to the rated heat rejection capacity at the rated condensing temperature.

Field: Water Inlet Node Name

A node name for the water-side condenser inlet must be provided.

Field: Water Outlet Node Name

A node name for the water-side condenser outlet must be provided.

Field: Water-Cooled Loop Flow Type

The type of flow loop should be specified. The two choices are **VariableFlow**, in which a Pump:VariableSpeed must be included in the plant loop, or **ConstantFlow**, in which the loop circuit has a constant flow rate, typically associated with a Pump:ConstandSpeed object. If the flow type is VariableFlow, the flow needed to remove the condenser heat energy will be calculated and requested of the pump. If the flow type is ConstantFlow, the outlet water temperature will be determined based on the fixed loop flow rate and heat energy to be removed. The default type is VariableFlow. Refer to additional discussion in the Engineering Reference.

Field: Water Outlet Temperature Schedule Name

When the water-cooled loop flow type is “VariableFlow”, the name of a schedule (Ref: Schedule) that defines the desired condenser water outlet temperature must be provided. The schedule may define an outlet temperature that varies through time.

Field: Water Design Flow Rate

When the water-cooled loop flow type is “ConstantFlow”, this is the design water flow rate in m³/s that will be requested initially. This requested flow will be passed to the loop simulation, and resulting actual flow will be dependent upon supply system capabilities (e.g., pump capability). The design flow rate must always be less than the maximum flow rate, defined below.

Field: Water Maximum Flow Rate

This numeric field is the maximum water flow rate in m³/s that will be allowed through the condenser. When the loop flow type is Variable Flow, if the calculated flow rate is higher than the maximum flow rate, an error message will be generated, and the flow rate will be reset to the maximum flow rate.

Field: Maximum Water Outlet Temperature

This numeric field specifies the maximum allowed water temperature in degrees C leaving the condenser. The default value is 55 degrees C.

Field: Minimum Water Inlet Temperature

This numeric field specifies the minimum allowed water temperature in degrees C entering the compressor rack condenser. The default value is 10 degrees C. Refer to additional discussion in the Engineering Reference.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature System"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions.

Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

FOR CONDENSERS ON SYSTEMS SERVING CASES AND/OR WALKINS:***Refrigeration System Condenser Heat Transfer Rate [W]***

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

Refrigeration System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

Refrigeration System Condenser Total Recovered Heat Rate [W]

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose.

Refrigeration System Condenser Total Recovered Heat Energy [J]

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose for the timestep being reported.

Refrigeration System Condenser Heat Recovered for Non-Refrigeration Purposes Rate [W]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

Refrigeration System Condenser Heat Recovered for Non-Refrigeration Purposes Energy [J]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

Refrigeration System Condenser Heat Recovered for Refrigeration Defrost Rate [W]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system..

Refrigeration System Condenser Heat Energy Recovered for Refrigeration Defrost Energy [J]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

Refrigeration System Condenser Water Mass Flow Rate [kg/s]

This is the mass flow rate of the water used to cool the condenser in kg/s.

FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:***Refrigeration Chiller System Condenser Heat Transfer Rate [W]***

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

Refrigeration Chiller System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

Refrigeration Chiller System Condenser Total Recovered Heat Rate [W]

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose.

Refrigeration Chiller System Condenser Total Recovered Heat Energy [J]

This is the total heat recovered from the condenser refrigerant inlet flow for any purpose for the timestep being reported.

Refrigeration Chiller System Condenser Heat Recovered for Non-Refrigeration Purposes Rate [W]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating.

Refrigeration Chiller System Condenser Heat Recovered for Non-Refrigeration Purposes Energy [J]

This is the total heat recovered from the condenser inlet flow for purposes such as water or air heating for the timestep being reported.

Refrigeration Chiller System Condenser Heat Recovered for Refrigeration Defrost Rate [W]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system.

Refrigeration Chiller System Condenser Heat Energy Recovered for Refrigeration Defrost Energy [J]

This is the total heat recovered from the condenser inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

Refrigeration Chiller System Condenser Water Mass Flow Rate [kg/s]

This is the mass flow rate of the water used to cool the condenser in kg/s.

Refrigeration:Condenser:Cascade

The refrigeration system requires a single condenser. The cascade condenser object is one of four options for this condenser. The cascade condenser is unlike the other condenser options because it rejects heat to another, higher-temperature, refrigeration system. That is, the cascade condenser acts as a heat rejection object for one system, but acts as a refrigeration load for another system. Therefore, this object will be referenced twice: first for the system rejecting heat (see the field Refrigeration Condenser Name for the object Refrigeration:System), and second for the system absorbing the heat (see the input for the field Refrigeration Transfer Load or TransferLoad List Name for the object Refrigeration:System or the field Cascade Condenser Name or Secondary System Name for the object Refrigeration:TransferLoadList).

Manufacturer's data is required for the rated condensing temperature and the rated approach temperature difference. The user must also specify the condensing temperature control type. There are two choices. The user can specify "Fixed" and the condensing temperature will be held constant at the input value. The user can specify "Float" if they want the condensing temperature to be set by other refrigeration loads served by the higher-temperature system.

The rated heat rejection capacity is not used except as a rough input value check on the overall system sizing. Optional input is provided to help the user compare refrigerant inventories for different systems. These inputs represent the design values for the refrigerant inventory within the condenser, within a receiver beneath the condenser, and in the liquid pipes between the condenser and the refrigerated cases.

Field: Name

Identifies a particular condenser that rejects heat for a single refrigeration system. The name must be unique and will be validated against all the condenser names (ref: Refrigeration:Condenser:*) in the input file, including names used for air-cooled, evaporative-cooled, and water-cooled condensers.

Field: Rated Condensing Temperature

This numeric field provides the rated condensing temperature (C).

Field: Rated Approach Temperature Difference

This numeric field provides the rated difference (Delta C) between the saturated condensing temperature for the system rejecting heat and the saturated evaporating refrigerant temperature for the system absorbing heat. The default value is 3.0 C.

Field: Rated Effective Total Heat Rejection Rate

This numeric field should be the rated heat rejection effect (W). Be sure the rating corresponds to the correct refrigerant(s). This value is used for system sizing error checking.

Field: Condensing Temperature Control Type

The type of control used to set the saturated condensing temperature. Valid choices are **Fixed** and **Float**. If the field is blank, **Fixed** will be used. **Fixed** will hold the condensing temperature constant at the value specified. **Float** will consider the specified input as a minimum condensing temperature. This value will be compared to the evaporating temperatures required by other loads on the higher-temperature refrigeration system, and will use the lowest temperature required to meet those loads, along with the Approach Temperature Difference, to set the condensing temperature.

Field: Condenser Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the condenser (kg) specified by the manufacturer, under standard rating conditions. This refrigerant is on the side of the condenser rejecting heat, not on the side of the condenser absorbing the heat.

Field: Condensate Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate receiver (kg) specified by the manufacturer or system designer, under standard rating conditions.

Field: Condensate Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the condensate piping (kg) specified by the system designer, under standard rating conditions.

The following is an example input for a cascade condenser.

```
Refrigeration:Condenser:Cascade,
  CascadeCondenser1 ,           !- Name
  -4. ,                      !- Rated Condensing Temperature {C}
  3. ,                       !- Rated Approach Temperature Difference {DeltaC}
  20000.0 ,                  !- Rated Effective Total Heat Rejection Rate {W}
  Fixed;                     !- Condensing Temperature Control Type
```

Refrigeration:Condenser:Cascade Outputs

FOR CONDENSERS COOLING SYSTEMS SERVING CASES AND/OR WALKINS: Zone,Average, Refrigeration System Condenser Heat Transfer Rate [W] Zone, Sum, Refrigeration System Condenser Heat Transfer Energy [J] FOR CONDENSERS COOLING SYSTEMS SERVING AIR CHILLERS: HVAC,Average, Refrigeration System Condenser Heat Transfer Rate [W] HVAC, Sum, Refrigeration System Condenser Heat Transfer Energy [J]
--

FOR CONDENSERS ON SYSTEMS SERVING CASES AND/OR WALKINS:

Refrigeration System Condenser Heat Transfer Rate [W]

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

Refrigeration System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

FOR CONDENSERS ON SYSTEMS SERVING AIR CHILLERS:**Refrigeration Chiller System Condenser Heat Transfer Rate [W]**

This is the total heat transfer across the condenser (i.e., compressor energy and refrigeration loads) in Watts.

Refrigeration Chiller System Condenser Heat Transfer Energy [J]

This is the total heat energy flowing across the condenser for the timestep being reported.

Refrigeration:GasCooler:AirCooled

The transcritical refrigeration system requires a single gas cooler to reject the system heat. The total heat of rejection is characterized by a linear relationship between the difference between the outside dry-bulb and gas cooler outlet temperatures. The rated gas cooler fan power and fan speed control type must be specified. If the gas cooler is not at ground level, the user may specify an air inlet node name (Ref. OutdoorAir:Node name). Optional input is provided to help the user track refrigerant inventories. These inputs represent the design values for the refrigerant inventory within the gas cooler, within a receiver, and in the liquid pipes between the gas cooler and the refrigerated cases.

Field: Name

Identifies a particular gas cooler that rejects heat for a single refrigeration system. The name must be unique and will be validated against all the gas cooler names (Ref. Refrigeration:GasCooler:AirCooled) in the input file.

Field: Rated Total Heat Rejection Rate Curve Name

This field is the name of a curve object defining the gas cooler heat rejection as a function of the difference between the gas cooler outlet and entering air temperatures. The curve should be linear (Curve:Linear). See the Engineering Reference for more discussion on the curve coefficients.

Field: Gas Cooler Fan Speed Control Type

The type of fan speed control used by the gas cooler fan. Valid choices are Fixed, FixedLinear, VariableSpeed, and TwoSpeed. If the field is blank, Fixed will be used. Note that fan energy consumption for the air-cooled gas cooler is computed in the same way as that of the air-cooled condenser. For further information on fan energy calculations, see the discussion regarding air-cooled condenser fan energy in the Engineering Reference.

Field: Rated Fan Power

This numeric field specifies the rated fan power (W) specified by the manufacturer, under standard rating conditions. If this field is blank, the default value of 5000 W will be used.

Field: Minimum Fan Air Flow Ratio

Fan controls often include a minimum air flow ratio to avoid overheating the fan motor or for other reasons. This numeric field should be between 0. and 1. and has a default value of 0.2.

Field: Transition Temperature

This is the temperature (C) at which the gas cooler and the refrigeration system transitions between subcritical and transcritical operation. If this field is blank, the default value of 27.0°C will be used.

Field: Transcritical Approach Temperature

This is the temperature difference (C) between the refrigerant (CO_2) exiting the gas cooler and the air entering the gas cooler during transcritical operation. If this field is blank, the default value of 3.0°C will be used.

Field: Subcritical Temperature Difference

This is the temperature difference (C) between the condensing temperature and the ambient air temperature during subcritical operation. If this field is blank, the default value of 10.0°C will be used.

Field: Minimum Condensing Temperature

This numeric field specifies the minimum condensing temperature (C) required to maintain stable subcritical operation. If this field is blank, the default value of 10.0°C will be used.

Field: Air Inlet Node Name

This optional alpha field contains the name of the node from which the gas cooler draws its outdoor air. If this field is left blank, the outdoor air dry-bulb temperature entering the gas cooler is taken directly from the weather data. If this field is not blank, this node name must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref. Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

Field: Gas Cooler Refrigerant Operating Charge Inventory

This numeric field specifies the amount of refrigerant present within the gas cooler (kg) specified by the manufacturer, under standard rating conditions. If this field is blank, the default value of 0.0 kg will be used.

Field: Gas Cooler Receiver Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the gas cooler receiver (kg) specified by the manufacturer or system designer, under standard rating conditions. If this field is blank, the default value of 0.0 kg will be used.

Field: Gas Cooler Outlet Piping Refrigerant Inventory

This numeric field specifies the amount of refrigerant present within the gas cooling outlet piping (kg) specified by the system designer, under standard rating conditions. If this field is blank, the default value of 0.0 kg will be used.

The following is an example input for an air-cooled gas cooler.

```

Transcritical Refrigeration System Gas Cooler Heat Transfer Rate [W]

This output is the total heat transfer rate from the gas cooler in Watts, and includes compressor energy and the refrigeration load.

Transcritical Refrigeration System Gas Cooler Heat Transfer Energy [J]

This output is the total heat transferred from the gas cooler to the surroundings, in Joules, for the timestep being reported.

Transcritical Refrigeration System Gas Cooler Fan Electric Power [W]

This output is the electric input to the system's gas cooler fan(s) in Watts.

Transcritical Refrigeration System Gas Cooler Fan Electric Consumption [J]

This is the electricity consumption of the system's gas cooler fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Transcritical Refrigeration System Gas Cooler Outlet Temperature [C]

This output is the temperature (in C) of the refrigerant exiting the gas cooler.

Transcritical Refrigeration System Gas Cooler Outlet Pressure [Pa]

This output is the pressure (in Pa) of the refrigerant exiting the gas cooler.

Transcritical Refrigeration System Gas Cooler Heat Recovered for Refrigeration Defrost Rate [W]

This is the total heat recovered from the gas cooler inlet flow for defrost purposes within the refrigeration system.

Transcritical Refrigeration System Gas Cooler Heat Recovered for Refrigeration Defrost Energy [J]

This is the total heat recovered from the gas cooler inlet flow for defrost purposes within the refrigeration system for the timestep being reported.

Refrigeration:TransferLoadList

A refrigeration system may provide cooling to other, secondary, systems through either a secondary loop or a cascade condenser (Ref. Refrigeration:SecondarySystem and Refrigeration:Condenser:Cascade). If multiple transfer loads are served by a single primary system, use this list to group them together for reference by the primary system (see the field "Refrigeration Transfer Load or TransferLoad List Name" in the Refrigeration:System object).

Field: Name

A unique user-assigned name for an instance of a refrigeration transfer load list. Any reference to this list by another object will use this name. In particular, the primary refrigeration system absorbing the heat from all the loads listed here will use this name to reference those loads.

Field: Cascade Condenser Name or Secondary System Name

Identifies a cascade condenser or secondary loop that is cooled, along with the other transfer loads listed here, by a single system. The name will be validated against the Refrigeration:SecondarySystem and Refrigeration:Condenser:Cascade names in the input file (the name will also be compared against all the other condenser names, but an error will be issued if it refers to any type of condenser other than a cascade condenser).

The list is extensible; ten fields are provided in the IDD.

The following is an example input for a transfer load list.

```
Refrigeration:TransferLoadList,
  MedTempTransferLoads ,      !- Name
  CascadeCondFrozen,          !- Cascade Condenser Name or Secondary System Name
  SecondLoopDairy;           !- Cascade Condenser Name or Secondary System Name
```

Refrigeration:SecondarySystem

A refrigeration secondary system works in conjunction with refrigerated cases and walkins (Ref. Refrigeration:SecondarySystem, Refrigeration:CaseAndWalkInList, Refrigeration:Case, and Refrigeration:WalkIn) to simulate the performance of a secondary loop supermarket refrigeration system. Heat from the refrigeration loads served by the secondary loop is absorbed by a primary refrigeration system (ref: Refrigeration:System). The SecondarySystem object simulates a heat exchanger that is an evaporator, or refrigeration load, on the primary refrigeration system.

The inputs for the refrigeration secondary system object include a name, which is also referenced to identify the load placed upon the primary refrigeration system. The inputs that describe the loads placed upon the secondary loop include the name of a single refrigerated case, the name of a single walk-in cooler, or a list of cases and walkin coolers. The circulating fluid type specifies whether or not the secondary fluid remains in the liquid state throughout the loop (e.g., a glycol or brine solution) or undergoes a partial phase change while serving the refrigeration loads (e.g., a CO₂ liquid overfeed system). The circulating fluid

name must also be specified and must correspond to a name used to provide the fluid properties.

If the secondary fluid remains a liquid, the heat exchanger between the primary and secondary systems functions as an evaporator on the primary side and chills the circulating fluid on the secondary side. Inputs that describe the evaporator performance at rated conditions are used to calculate the heat exchanger effectiveness. These values include the rated evaporator capacity (which can be specified in terms of energy or fluid flow rate), the rated evaporating temperature, the rated approach temperature difference, and the rated range temperature difference.

If the secondary fluid undergoes a partial phase change, the heat exchanger between the primary and secondary systems functions as an evaporator on the primary side and as a condenser on the secondary side. The evaporator capacity, evaporating temperature, and approach temperature difference, all at full-load design conditions, are input.

The balance of the secondary system object describes the pumping system. The pumping options include a single constant speed pump, multiple constant speed pumps, or a variable frequency-drive pump. The user can also keep track of distribution piping and receiver shell heat gains.

Field: Name

A unique user-assigned name for an instance of a refrigeration secondary system. Any reference to this refrigeration secondary system by another object will use this name. In particular, the primary refrigeration system absorbing the heat from this system will use this name to define that load.

Field: Refrigerated Case or WalkIn or CaseAndWalkInList Name

Identifies a single case, or walkin, or a particular list of refrigerated cases and walkins, that are cooled by this refrigeration secondary system. The name will be validated against the case, walkin, and CaseAndWalkInList names (ref. Refrigeration:Case, Refrigeration:WalkIn and Refrigeration:CaseAndWalkInList) in the input file.

Field: Circulating Fluid Type

Specifies whether the fluid is always liquid (e.g., glycol solution), or undergoes a partial phase change (e.g., CO₂ liquid overfeed system). The options are “FluidAlwaysLiquid” and “FluidPhaseChange”.

Field: Circulating Fluid Name

The name of the secondary circulating fluid.

For “FluidAlwaysLiquid”, this name must correspond to either an ethylene or propylene glycol (ref: FluidProperties:GlycolConcentration) or to a user-defined glycol (ref: FluidProperties:Name and FluidProperties: GlycolConcentration) in the input file. Note that the corresponding property data, including FluidProperties:Concentration, FluidProperties:Temperatures, and FluidProperties:GlycolConcentration must also be included in the input file and are provided in GlycolPropertiesRefData.idf for typical ethylene and propylene glycols.

For “FluidPhaseChange”, the refrigerant used by the secondary system must be listed in the FluidProperties:Name object. The corresponding property data must also be supplied in the input file. Property data for many refrigerants, including R11, R123, R134A, R12, R22, R404A, R507A, R410A, and R744, are available in FluidPropertiesRefData.idf.

Field: Evaporator Capacity

For “FluidAlwaysLiquid”, this numeric field should be the rated heat evaporator capacity (W). Be sure the rating corresponds to the correct refrigerant and secondary circulating fluid. If this variable is specified and the rated evaporator flow rate for secondary fluid is not, then the flow rate will be calculated. At least one of these two input variables is required.

For “FluidPhaseChange”, this numeric field should be the evaporator capacity (W) at full-load design conditions. If this input is left blank, the capacity will be set to the sum of the capacities of the cases and walk-ins served by the secondary loop plus the pump motor load at full-load design conditions.

Field: Evaporator Flow Rate for Secondary Fluid

For “FluidAlwaysLiquid” systems, this is the rated evaporator secondary fluid flow rate in m³/s. If this variable is specified and the rated evaporator capacity in watts is not, then the rated capacity will be calculated. At least one of these two input variables is required.

For “FluidPhaseChange”, this field is not used (see “Phase Change Circulating Rate”).

Field: Evaporator Evaporating Temperature

This numeric field provides the evaporating temperature (C) corresponding to the evaporator capacity. This is the evaporating temperature on the primary side of the heat exchanger used to chill or condense the secondary loop circulating fluid. It is NOT the temperature in any cases or walkins served by the secondary loop.

Field: Evaporator Approach Temperature Difference

For “FluidAlwaysLiquid”, this numeric field is the rated temperature difference (DeltaC) between the circulating secondary fluid leaving the heat exchanger and the heat exchanger’s evaporating temperature.

For “FluidPhaseChange”, this is the temperature difference (DeltaC) between the primary refrigerant evaporating and secondary refrigerant condensing temperatures at full-load design conditions.

Field: Evaporator Range Temperature Difference

For “FluidAlwaysLiquid”, this numeric field is the rated temperature difference (DeltaC) between the circulating secondary fluid entering and leaving the heat exchanger. This value is not used for “FluidPhaseChange”.

Field: Number of Pumps in Loop

This numeric field provides the integer number of pumps used to circulate the secondary heat transfer fluid. The default value is 1. Unless a variable speed pump is specified, pump energy will be calculated in linear steps to achieve the necessary flow rate.

Field: Total Pump Flow Rate

This is the secondary fluid circulating flow rate in m³/s at full-load design conditions. For “FluidAlwaysLiquid”, if no value is input, the Evaporator Flow Rate for Secondary Fluid will be used. For “FluidPhaseChange”, if no value is input, the flow rate will be calculated using the Evaporator Capacity and the PhaseChange Circulating Rate.

Field: Total Pump Power

This numeric field should be the pump power (W) at full-load design conditions. Be sure the rating corresponds to the correct secondary circulating fluid at the design fluid temperature. EITHER the Total Pump Power OR the Total Pump Head is required.

Field: Total Pump Head

This numeric field should be the design pressure drop, or head, across the secondary loop (Pa) at full load design conditions. Be sure the rating corresponds to the correct secondary circulating fluid at the design fluid temperature. EITHER the Total Pump Power OR the Total Head is required.

Field: PhaseChange Circulating Rate

This field is not used for “FluidAlwaysLiquid”.

For “FluidPhaseChange”, the Circulating Rate is defined as the total mass flow at the pump divided by the mass flow rate of vapor returning to the separator. Values between 2.1 and 3 are common for CO₂ systems and the default is 2.5. If Total Pump Flow Rate is also defined, the PhaseChange Circulating Rate will only be used to check whether the two values are consistent.

Field: Pump Drive Type

Specifies whether the pump(s) is constant speed or variable speed. The options are “Constant” and “Variable”. The default is “Constant”.

Field: Variable Speed Pump Cubic Curve Name

The name of a **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of the variable speed pump power (and the associated load on the secondary refrigeration load) at off-rated conditions. The curve should be normalized to have the value of 1.0 at full-load design conditions. The variable speed pump cubic curve name is used only for the a pump drive type of “Variable”.

Field: Pump Motor Heat to Fluid

This choice field determines how much of the pump motor heat will be added to the circulating secondary fluid. This represents the motor efficiency for a non-hermetic motor. The default is 0.85. For a semi-hermetic motor, enter 1.0. The value entered must be between 0.5 and 1.0.

Field: Sum UA Distribution Piping

This optional field is typically used when trying to compare the impact of pipe heat gains on system performance, particularly in comparing a DX system to a secondary system. Enter the value for secondary loop distribution piping heat gain (in W/C). That is, sum up the product of the pipe insulation conductance times the outer piping insulation surface area. Please see the Engineering Reference for guidance in calculating this value.

Field: Distribution Piping Zone Name

This optional field is used when trying to determine the impact of pipe heat gains on system performance, particularly in comparing a DX system to a secondary system. (If the previous field, Sum UA Distribution Piping, is blank, this field will not be used.) Enter the name of the zone where the Distribution piping is located. The distribution piping heat gains will be calculated based upon the air temperature within this zone and will count as a cooling credit for this zone.

Field: Sum UA Receiver/Separator Shell

This optional field is typically used when trying to compare the impact of refrigeration component heat gains on system performance, particularly in comparing a conventional primary DX system to a secondary system. Enter the value for receiver/separatator heat gain (in W/C). That is, sum up the product of the tank insulation conductance times the outer tank insulation surface area. Please see the Engineering Reference for guidance in calculating this value.

Field: Receiver/Separator Zone Name

This optional field is used when trying to determine the impact of refrigeration component heat gains on system performance, particularly in comparing a conventional primary DX system to a secondary system. (If the previous field, Sum UA Receiver/Separator, is blank, this field will not be used.) Enter the name of the zone where the receiver/separatator is located. The heat gains will be calculated based upon the air temperature within this zone and will count as a cooling credit for this zone.

Field: Evaporator Refrigerant Inventory

The secondary loop is chilled by a primary system via a heat exchanger. This field is the refrigerant inventory on the cold (primary) side of that heat exchanger, in kg. The default value is zero.

Field: End-Use Subcategory

This field allows the specification of a user-defined end-use subcategory (e.g., "Low Temperature Rack"). A new meter for reporting is created for each unique subcategory (Ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is left blank, the equipment will be assigned to the "General" end-use subcategory.

The following is an example input for a brine-type ("FluidAlwaysLiquid")refrigeration secondary system.

FOR SECONDARY SYSTEMS SERVING CASES AND/OR WALKINS:

Refrigeration Secondary Loop Pump Electric Power [W]

This output is the total electric power input to the pump(s) in Watts.

Refrigeration Secondary Loop Pump Electric Consumption [J]

This is the electricity consumption of the system's pump(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Secondary Loop Refrigeration Heat Transfer Rate [W]

This is the amount of refrigeration provided to the cases and walkins served by the secondary loop in W.

Refrigeration Secondary Loop Refrigeration Heat Transfer Energy [J]

This is the amount of refrigeration provided to the cases and walkins served by the secondary loop in Joules for the timestep being reported.

Refrigeration Secondary Loop Total Heat Transfer Rate [W]

This is the total amount of refrigeration load placed upon the primary refrigeration system (including loads due to the cases and walkins plus the loads from the secondary loop pumps and any energy absorbed by the loop via pipe heat gains) in W.

Refrigeration Secondary Loop Total Heat Transfer Energy [J]

This is the total amount of energy placed upon the primary refrigeration system by the secondary loop in Joules for the timestep being reported.

Refrigeration Secondary Loop Estimated Refrigerant Inventory [kg]

This output is the sum of the input inventory values for the cases and walkins and the refrigerant circulating through the loop.

Refrigeration Secondary Loop Coolant Vol Flow [m³/s]

This output is the calculated volume flow through the pumps for this secondary loop.

Refrigeration Secondary Loop Pipe Heat Gain Rate [W]

This output is the total heat transferred to the pipes in Watts.

Refrigeration Secondary Loop Pipe Heat Gain Energy [J]

This is the total heat transferred to the pipes in Joules for the timestep being reported.

Refrigeration Secondary Loop Receiver Heat Gain Rate [W]

This output is the total heat transferred to the receiver in Watts.

Refrigeration Secondary Loop Receiver Heat Gain Energy [J]

This is the total heat transferred to the receiver in Joules for the timestep being reported.

FOR SECONDARY SYSTEMS SERVING AIR CHILLERS:***Refrigeration Chiller Secondary Loop Pump Electric Power [W]***

This output is the total electric power input to the pump(s) in Watts.

Refrigeration Chiller Secondary Loop Pump Electric Consumption [J]

This is the electricity consumption of the system's pump(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Plant (Ref. Report Meter).

Refrigeration Chiller Secondary Loop Refrigeration Heat Transfer Rate [W]

This is the amount of refrigeration provided to the cases and walkins served by the secondary loop in W.

Refrigeration Chiller Secondary Loop Refrigeration Heat Transfer Energy [J]

This is the amount of refrigeration provided to the cases and walkins served by the secondary loop in Joules for the timestep being reported.

Refrigeration Chiller Secondary Loop Total Heat Transfer Rate [W]

This is the total amount of refrigeration load placed upon the primary refrigeration system (including loads due to the cases and walkins plus the loads from the secondary loop pumps and any energy absorbed by the loop via pipe heat gains) in W.

Refrigeration Chiller Secondary Loop Total Heat Transfer Energy [J]

This is the total amount of energy placed upon the primary refrigeration system by the secondary loop in Joules for the timestep being reported.

Refrigeration Chiller Secondary Loop Estimated Refrigerant Inventory [kg]

This output is the sum of the input inventory values for the cases and walkins and the refrigerant circulating through the loop.

Refrigeration Chiller Secondary Loop Coolant Vol Flow [m³/s]

This output is the calculated volume flow through the pumps for this secondary loop.

Refrigeration Chiller Secondary Loop Pipe Heat Gain Rate [W]

This output is the total heat transferred to the pipes in Watts.

Refrigeration Chiller Secondary Loop Pipe Heat Gain Energy [J]

This is the total heat transferred to the pipes in Joules for the timestep being reported.

Refrigeration Chiller Secondary Loop Receiver Heat Gain Rate [W]

This output is the total heat transferred to the receiver in Watts.

Refrigeration Chiller Secondary Loop Receiver Heat Gain Energy [J]

This is the total heat transferred to the receiver in Joules for the timestep being reported.

Additional Refrigeration Outputs Available for Each Zone

Multiple refrigeration cases and walkins may be located within a single zone. Each zone may also exchange heat with refrigeration system suction piping, secondary loop distribution piping, and secondary loop receivers. Output variables have been prepared to sum up the total heat exchange due to all refrigeration objects within a single zone. The output variables that start with "Zone Refrigeration" do not account for refrigeration provided by refrigeration chiller sets or any piping from systems serving air chillers. The output variables that start with "Zone Chillers" account for all the refrigeration system elements serving air chillers.

Additional Refrigeration Outputs for Each Zone

FOR THE SUM OF ALL COOLING SYSTEMS SERVING CASES AND/OR WALKINS:

Zone Refrigeration: Total Sensible Heat Transfer Rate [W]

This output is the total sensible heat transfer between all refrigeration objects located in the zone in Watts. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

Zone Refrigeration: Total Sensible Heat Transfer Energy [J]

This is the total sensible heat transfer between all refrigeration objects located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

Zone Refrigeration: Total Latent Heat Transfer Rate [W]

This output is the total latent heat transfer between all refrigeration objects located in the zone in Watts. A negative value will be reported when the refrigeration equipment provides dehumidification (thereby reducing the zone latent load).

Zone Refrigeration: Total Latent Heat Transfer Energy [J]

This is the total latent heat transfer between all refrigeration objects located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration equipment provides dehumidification (thereby reducing the zone latent load).

Zone Refrigeration: Total Heat Transfer Rate [W]

This output is the total heat transfer (sensible plus latent) between all refrigeration objects located in the zone in Watts. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

Zone Refrigeration: Total Heat Transfer Energy [J]

This is the total heat transfer (sensible plus latent) between all refrigeration objects located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

Zone Refrigeration Sensible Cooling Rate [W]

This output is the total sensible cooling from all refrigeration objects located in the zone in Watts.

Zone Refrigeration Sensible Cooling Energy [J]

This is the total sensible cooling from all refrigeration objects located in the zone in Joules for for the timestep being reported.

Zone Refrigeration Heating Rate [W]

This output is the total heating from all refrigeration objects located in the zone in Watts.

Zone Refrigeration Heating Energy [J]

This is the total heating from all refrigeration objects located in the zone in Joules for for the timestep being reported.

Zone Refrigeration Total Cooling Rate [W]

This output is the total cooling (sensible plus latent) from all refrigeration objects located in the zone in Watts.

Zone Refrigeration Total Cooling Energy [J]

This is the total cooling (sensible plus latent) from all refrigeration objects located in the zone in Joules for for the timestep being reported.

FOR THE SUM OF ALL COOLING SYSTEMS SERVING AIR CHILLERS:***Zone Chillers Heating Rate [W]***

This output is the total heating from all air chillers located in the zone in Watts.

Zone Chillers Heating Energy [J]

This is the total heating from all air chillers located in the zone in Joules for for the timestep being reported.

Zone Chillers Sensible Cooling Rate [W]

This output is the total sensible cooling from all air chillers located in the zone in Watts.

Zone Chillers Sensible Cooling Energy [J]

This is the total sensible cooling from all air chillers located in the zone in Joules for for the timestep being reported.

Zone Chillers Sensible Heat Transfer Rate [W]

This output is the total sensible heat transfer from all air chillers located in the zone in Watts. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

Zone Chillers Sensible Heat Transfer Energy [J]

This is the total sensible heat transfer from all air chillers located in the zone in Joules for for the timestep being reported. A negative value will be reported when the refrigeration objects cool (that is, remove heat from) the zone.

Zone Chillers Latent Cooling Rate [W]

This output is the total latent cooling from all air chillers located in the zone in Watts.

Zone Chillers Latent Cooling Energy [J]

This is the total latent cooling from all air chillers located in the zone in Joules for for the timestep being reported.

Zone Chillers Water Removed From Zone Air Rate [kg/s]

This is the total amount of water removed by all air chillers located in the zone in kg/s for for the timestep being reported.

Zone Chillers Total Cooling Rate [W]

This output is the total cooling (sensible plus latent) from all air chillers located in the zone in Watts.

Zone Chillers Total Cooling Energy [J]

This is the total cooling (sensible plus latent) from all air chillers located in the zone in Joules for for the timestep being reported.

Refrigeration:AirChiller

The Refrigeration:AirChiller object works in conjunction with a refrigeration chiller set, compressor rack, a refrigeration system, or a refrigeration secondary system object (Ref. ZoneHvac:RefrigerationChillerSet, and a Refrigeration:CompressorRack, Refrigeration:System, or Refrigeration:SecondarySystem) to simulate the performance of an air chiller, similar to one found in a refrigerated warehouse. The air chiller model uses information at rated conditions along with the zone conditions to determine performance. Energy use for fans and heaters is modeled based on inputs for nominal power, schedules,

and control type. The refrigeration chiller model accounts for the sensible and latent heat exchange with the surrounding environment.

The refrigeration chiller cooler object inputs include a name, an availability schedule name, the rated cooling capacity, the rated operating temperature, the rated cooling source temperature, the rated total heating power and heating power schedule, the rated fan power and schedules, defrost type, defrost control type, defrost schedule name, drip-down schedule name, defrost power, the portion of the defrost energy used to melt ice (only for temperature termination control type), and refrigerant inventory.

Chiller coils are rated under multiple conventions. Each rating is typically based upon a selected fin material and refrigerant cycle, with correction factors for other materials or refrigerants. Fields are provided here for those correction factors. The performance of all chiller coils depends upon the inlet air temperature, relative humidity, and flow rate. Multiple methods of expressing this relationship are provided here to accommodate the wa information is provided by different manufacturers.

Field: Name

A unique user-assigned name for an instance of a refrigeration chiller. Any reference to this refrigeration chiller by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigeration chiller can operate during a given time period. A schedule value greater than 0 (maximum schedule value of 1.0 is typically used) indicates that the refrigeration chiller will operate during a given time period. A value equal to 0 denotes that the case does not operate (everything is OFF: refrigeration, fans, lights, anti-sweat, etc.). Typically the refrigeration chiller will operate throughout the day (i.e., the schedule will contain 1 for all time periods); however, refrigeration chillers require maintenance and/or cleaning and this can be modeled accordingly using this schedule if desired. If this field is left blank, the default schedule has a value of 1 for all time periods.

Field: Capacity Rating Type

The type of capacity rating used for this refrigeration chiller. Valid choices are UnitLoadFactorSensibleOnly, CapacityTotalSpecificConditions, EuropeanSC1Standard, EuropeanSC1NominalWet, EuropeanSC2Standard, EuropeanSC2NominalWet, EuropeanSC3Standard, EuropeanSC3NominalWet, EuropeanSC4Standard, EuropeanSC4NominalWet, EuropeanSC5Standard, and EuropeanSC5NominalWet. In each case, select the rating option that corresponds to the expected service conditions. For example, U.S. manufacturers quote a separate Unit Load Factor for wet or frosted coils. If the evaporating temperature is less than 0C, input the frosted coil value. Within the European convention, select SC1, 2, 3, 4, or 5 depending upon the expected evaporating temperature. This field is required and there is no default value. Refer to the Engineering Reference for further information on these rating types. NOTE: If any of the European rating types are specified, the input must include the curve object: Table:OneIndependentVariable named "ChillerEuropeanWetCoilFactor". This can be taken from the RefrigeratedWarehouse example file.

NOTE – ONLY ONE OF THE FOLLOWING TWO FIELDS IS USED

Field: Rated Unit Load Factor

The sensible cooling capacity in watts (W/C) at rated conditions The value entered for this field must be greater than zero, with no default value. This value is only used if the Capacity Rating Type is UnitLoadFactorSensibleOnly. The value given must be based upon the difference between the chiller inlet and outlet air temperatures, not on the difference between the zone mean temperature and the outlet air temperature.

Field: Rated Capacity

The cooling capacity in watts (W) at rated conditions. The value entered for this field must be greater than zero, with no default value. This field is only used if the Capacity Rating Type is CapacityTotalSpecificConditions, EuropeanSC1Standard, EuropeanSC1NominalWet, EuropeanSC2Standard, EuropeanSC2NominalWet, EuropeanSC3Standard, EuropeanSC3NominalWet, EuropeanSC4Standard, EuropeanSC4NominalWet, EuropeanSC5Standard, or EuropeanSC5NominalWet. For CapacityTotalSpecificConditions, this capacity includes both sensible and latent at the conditions given in the next two fields. Note that the European Standard ratings are sensible only and the European Nominal ratings include latent capacity as well. The value given here must correspond to the capacity rating type given previously.

Field: Rated Relative Humidity

This field is ONLY used if the Capacity Rating Type is CapacityTotalSpecificConditions and represents the relative humidity at rated conditions, expressed as a percent. The default is 85.

Field: Rated Cooling Source Temperature

For a DX evaporator coil, enter the saturated evaporating temperature in °C. For a fluid coil, enter the fluid coil entrance temperature in °C. There is no default value. This number is used, with temperatures for other refrigeration loads on any one system, to set that system's minimum suction pressure or minimum circulating fluid temperature.

Field: Rated Temperature Difference DT1

The rated difference between the air entering the refrigeration chiller and the cooling source temperature in °C. The entered value for this field must be less than 20°C. There is no default value. Maximum Temperature Difference Between Inlet Air and Evaporating Temperature

```
\type real
\units deltaC
\minimum 0.0
\maximum 25.
\note The maximum difference between the air entering the refrigeration chiller and the
\note cooling source temperature in °C used to limit capacity during pull-down.
\note defaults to 1.3 times the Rated Temperature Difference DT1
```

Field: Maximum Difference Between Inlet Air and Evaporating Temperature

The maximum difference between the air entering the refrigeration chiller and the cooling source temperature in °C used to limit capacity during pull-down. The default is 1.3 times the Rated Temperature Difference DT1.

Field: Coil Material Correction Factor

This field is used to enter the manufacturer's correction factor for coil material corresponding to the rating previously input. the default is 1.0 (dimensionless).

Field: Refrigerant Correction Factor

This field is used to enter the manufacturer's correction factor for refrigerant corresponding to the rating previously input. the default is 1.0 (dimensionless). (Note, the refrigerant itself is specified for the detailed system or secondary loop providing the refrigerant to this coil.)

Field: Capacity Correction Curve Type

The type of capacity correction curve used to account for the impact of the room air conditions on the chiller capacity. Valid choices are LinearSHR60, QuadraticSHR, European, and TabularRHxDT1xTRoom. This field will default to LinearSHR60. Refer to the Engineering

Reference for further information on these curve types. The resulting correction factor for LinearSHR60, QuadraticSHR, and European types will be applied to the sensible capacity and must have output values between 1 and 2. The resulting correction factor for TabularRHxDT1xTRoom will be applied to the CapacityTotalSpecificConditions capacity and can have values between 0.2 and 2. If TabularRHxDT1xTRoom is used, the curve type within the table must be specified as "Quadratic".

NOTE: If European is selected, the input must include the curve object: Table:OneIndependentVariable named "ChillerEuropeanWetCoilFactor". This can be taken from the RefrigeratedWarehouse example file.

Field: Capacity Correction Curve Name

The name of the curve object defining the total refrigerating capacity. For types LinearSHR60 and QuadraticSHR, the independent variable is the Sensible Heat Ratio and the output values are between 1.0 and 2.0. For type European, the independent variables are inlet air temperature and relative humidity and this field will not be read. In that case, the input must include the curve object: Table:OneIndependentVariable named "ChillerEuropeanWetCoilFactor". This can be taken from the RefrigeratedWarehouse example file. For correction curve type TabularRHxDT1xTRoom, enter the name of a Table:MultiVariableLookup object that gives the total capacity (in W) as a function of RH, DT1, and Room Temperature; IN THAT ORDER.

Field: SHR60 Correction Factor

This field is only used when the capacity correction curve type is LinearSHR60. It should correspond to the capacity factor, that is, the total capacity divided by the sensible capacity corresponding to a Sensible Heat Ratio of 0.6. the default is 1.48 (dimensionless).

Field: Rated Total Heating Power

The total heating power in watts including drip-pan and any other heaters (W). This value is required and has no default value.

Field: Heating Power Schedule Name

The name of the schedule (ref: Schedule) that denotes the fraction of heater power that operates during a given time period. A schedule value of zero denotes that all heaters are off. A schedule value greater than 0 indicates that some portion of the total heater power will operate during that time period (maximum schedule value of 1.0 means all heaters are fully on). If this field is left blank, the default schedule has a value of 1 for all time periods.

Field: Fan Speed Control Type

The type of fan speed control used by the condenser fan. Valid choices are **Fixed**, **FixedLinear**, **VariableSpeed**, and **TwoSpeed**. If the field is blank, **Fixed** will be used. See the Engineering Reference for a discussion of this option's effect on fan energy consumption.

Field: Rated Fan Power

The cooling coil fan power in watts (W). This value has a default value of 375W. This fan is assumed to run continuously except during electric, hot brine, or hot gas defrost periods.

Field: Rated Air Flow

The cooling coil fan rated air flow in cubic meters per second (m³/s). This value has no default value and must be input.

Field: Minimum Fan Air Flow Ratio

The minimum fraction of the rated air flow for part-load fan operation, must be between 0. and 1.0. The default value is 0.2.

Field: Defrost Type

The type of defrost used for this refrigeration chiller. Valid choices are None, Off-Cycle, HotFluid, and Electric. The default defrost type is Electric if the field is blank. HotFluid includes both hot gas and hot brine defrost systems. Refer to the Engineering Reference for further information on how the different defrost types are modeled.

Field: Defrost Control Type

The type of defrost control used for this refrigeration chiller. Valid choices are TimeSchedule and TemperatureTermination. The default is TimeSchedule if the field is blank. Refer to the Engineering Reference for further information on how the different defrost controls are modeled.

Field: Defrost Schedule Name

The name of the schedule (ref: Schedule) that denotes when the refrigeration chiller requires defrosting. A schedule value of 1.0 indicates that defrost can be on during a given time period. A value equal to 0 denotes that the defrost is off. Defrost schedules normally repeat the duration and number of defrost cycles for each day of the year. The refrigeration chiller manufacturer typically provides this information with the product literature. If TemperatureTermination control type is used, the defrost schedule is used for the defrost cycle start time and the defrost cycle end time is not allowed to extend beyond the scheduled off time. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

Field: Defrost Drip-Down Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the refrigeration chiller requires additional time for draining condensate after the defrost period. A schedule value of 1.0 indicates that the defrost drip-down period is on during a given time period. A value equal to 0 denotes that the defrost drip-down period is over. The refrigeration chiller manufacturer typically provides this information with the product literature.

Each defrost drip-down period specified in this schedule should start at the same time as the corresponding defrost period specified in the schedule for Defrost Schedule, and the drip-down schedule defrost period should always be longer than or equal to the length of the defrost schedule time period. For example, if the defrost schedule contains a defrost period from 7:00 to 7:15, you would specify a case defrost drip-down period from 7:00 to 7:20 if you wanted to model a 5 minute condensate drip-down period after the regular defrost period. If no drip-down schedule is entered, then the defrost schedule (specified for the previous input field) will be used. The use of Compact Schedules (ref. Schedules) are ideal for this purpose.

Field: Defrost Power

The defrost power in watts. This input is required for hot-fluid (hot gas or hot brine), or electric defrost types. Refrigeration chiller manufacturers do not typically provide information on the heat input for hot gas and hot brine defrost. Information provided for electric defrost power can be substituted here for refrigeration chillers using hot-gas or hot-brine defrost if other information is not available. Only electric Defrost Types consume electricity during the defrost period. The entered value for this field must be greater than or equal to zero.

Field: Temperature Termination Defrost Fraction to Ice

When cooling coils go through a defrost cycle, only a portion of the defrost energy is actually used to melt the ice. The rest of the defrost energy goes to increasing the temperature of the coils themselves and to the refrigeration chiller environment. The Temperature Termination defrost control type calculates the end of the defrost cycle that corresponds to melting all the ice. Therefore, the user must input this fractional value. The default value is 0.7 for electric defrost and 0.3 for hot fluid defrost. Refer to the Engineering Reference for further information on how the defrost energy control types are modeled.

Field: Vertical Location

The vertical location for this refrigeration chiller. Valid choices are Floor, Middle, and Ceiling. The default is Middle if the field is blank. The vertical location is used to transform the mixed zone air temperature to the coil inlet air temperature. Refer to the Engineering Reference for further information on how the different vertical locations are modeled.

Field: Average Refrigerant Charge Inventory

The value of this optional field is the refrigerant inventory present in the refrigeration chiller during ordinary operation. The value is used to produce an estimate of the total refrigerant present in the refrigeration system. The value is entered in kg.

The following is an example input for a refrigeration air chiller.

```

Air Chiller Total Cooling Rate [W]

This field is the total (sensible plus latent) cooling rate of the Air Chiller evaporator coil in Watts.

Air Chiller Total Cooling Energy [J]

This field is the total (sensible plus latent) cooling of the Air Chiller evaporator coil in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Air Chiller Sensible Cooling Rate [W]

This field is the sensible cooling rate of the Air Chiller evaporator coil in Watts.

Air Chiller Sensible Cooling Energy [J]

This field is the sensible cooling of the Air Chiller evaporator coil in Joules over the timestep being reported.

Air Chiller Latent Cooling Rate [W]

This field is the latent cooling (dehumidification) rate of the Air Chiller evaporator coil in Watts.

Air Chiller Latent Cooling Energy [J]

This field is the latent cooling (dehumidification) of the Air Chiller evaporator coil in Joules over the timestep being reported.

Air Chiller Water Removal [kg/s]

This field is the latent cooling (dehumidification) of the Air Chiller evaporator coil in kilograms per second over the timestep being reported.

Air Chiller Total Auxiliary Electric Power [W]

This field is the total electricity (fan, heaters, lights, and electric defrost) used by the Air Chiller in Watts.

Air Chiller Total Auxiliary Electric Consumption [J]

This field is the electricity (fan, heaters, lights, and electric defrost) used by the Refrigeration chiller in Joules over the timestep being reported.

Air Chiller Fans Electric Power [W]

This field is the electric power input to the Air Chiller fan(s) in Watts.

Air Chiller Fan Electric Consumption [J]

This field is the electricity consumption of the Air Chiller fan(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Air Chiller Heaters Electric Power [W]

This field is the electric power input to the Air Chiller heaters in Watts.

Air Chiller Heaters Electric Consumption [J]

This field is the total electricity consumption of the Air Chiller heaters in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter).

Air Chiller Defrost Electric Power [W]

This field is the electric power input to the Air Chiller electric defrost heater(s) in Watts. This output is available if case defrost type is Electric.

Air Chiller Defrost Electric Consumption [J]

This field is the total electricity consumption of the Air Chiller electric defrost heater(s) in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Refrigeration, Group Key = Building (Ref. Report Meter). This output is available if case defrost type is Electric.

Air Chiller Sensible Heat Ratio

This field is the Sensible Cooling Energy Rate divided by the Total Cooling Energy Rate.

Air Chiller Frost Accumulation [kg]

This field is the total amount of frost present on the coil during the timestep being reported.

Air Chiller Total Cooling Zone Credit Rate [W]

This field is the rate of sensible cooling delivered to the zone in Watts. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

Air Chiller Total Cooling Zone Credit Energy [J]

This field is the amount of sensible cooling energy delivered to the zone in Joules. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

Air Chiller Sensible Cooling Zone Credit Rate [W]

This field is the rate of sensible cooling delivered to the zone in Watts. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

Air Chiller Sensible Cooling Zone Credit Energy [J]

This field is the amount of sensible cooling energy delivered to the zone in Joules. A positive value is reported when the zone is cooled by the air chiller, otherwise a zero is reported.

Air Chiller Heating Zone Credit Rate [W]

This field is the rate of sensible heating delivered to the zone in Watts. A positive value is reported when the zone is heated by the air chiller (typically only occurs during defrost), otherwise a zero is reported.

Air Chiller Heating Zone Credit Energy [J]

This field is the amount of sensible heating energy delivered to the zone in Joules. A positive value is reported when the zone is heated by the air chiller (typically only occurs during defrost), otherwise a zero is reported.

The following output variables are available for each zone served by any Air Chiller. An output variable identification is created for each zone exchanging energy with the Air Chiller. For example if the Air Chiller, “DairyRefrigeration chiller”, were exchanging energy with the zone, “SalesArea”, the output variable identification would be “DairyRefrigeration chillerInZoneSalesArea”.

Zone Chillers Sensible Cooling Rate [W]

This field is the rate of sensible cooling delivered to the zone, net of any auxiliary heat input, in Watts..

Zone Chillers Sensible Cooling Energy [J]

This field is the amount of sensible cooling energy, net of any auxiliary heat input, delivered to the zone in Joules.

Zone Chillers Latent Cooling Rate [W]

This field is the rate of latent cooling (dehumidification) delivered to the zone in Watts. A negative value will be reported when the Air Chiller provides dehumidification (thereby reducing the zone latent load).

Zone Chillers Water Removed from Zone Air Rate [kg/s]

This field is the rate of latent cooling (dehumidification) delivered to the zone in kg/s. A negative value (or zero) will be reported when the Air Chiller provides dehumidification (thereby reducing the zone latent load).

Zone Chillers Latent Cooling Energy [J]

This field is the amount of latent cooling (dehumidification) energy delivered to the zone in Joules. A negative value (or zero) will be reported when the Air Chiller provides dehumidification (thereby reducing the zone latent load).

Zone Chillers Total Cooling Rate [W]

This field is the total rate of cooling, sensible plus latent, delivered to the zone in Watts.

Zone Chillers Total Cooling Energy [J]

This field is the total amount of cooling, sensible plus latent, energy delivered to the zone in Joules.

Zone Chillers Heating Rate [W]

This field is the rate of net heating due to any auxiliary or defrost heat input delivered to the zone, in Watts.

Zone Chillers Heating Energy [J]

This field is the amount of net heating energy due to any auxiliary heat input, delivered to the zone in Joules.

Group – Zone Controls – Thermostats and Humidistats

Zone Control objects are used to control zone conditions to a specific setpoint. The four types of zone control are described in this section. They are, by name, ZoneControl:<name>.. These types are:

Thermostat – The object provides the traditional approach to space control using air temperatures. Each controlled zone contains a thermostat object.

Humidistat – The object is used to control a zone to a specified relative humidity.

Thermostat:ThermalComfort – The object provides a method to control a zone to a dry-bulb temperature setpoint based on a thermal comfort model (e.g. Fanger) and a user-specified thermal comfort setpoint schedule.

Thermostat:OperativeTemperature – The operative temperature control is formulated to reuse all of the traditional thermostat objects. One input object will be used for each thermal zone to indicate if that zone's thermostat control mode should be overridden to effect operative temperature control rather than traditional air temperature control. The user will still have to input all the traditional ZoneControl:Thermostat and setpoint objects.

Thermostat:TemperatureAndHumidity – This thermostat control works together with the traditional ZoneControl:Thermostat object to modify temperature control based on zone air humidity conditions. Currently, this object resets the thermostat's cooling setpoint temperature downward based on elevated zone air humidity levels, typically yielding additional cooling coil operation and associated dehumidification. A ZoneControl:Thermostat:TemperatureAndHumidity object should be specified to indicate if a zone's traditional thermostat control mode should be overridden to provide enhanced dehumidification. The user must still input the traditional ZoneControl:Thermostat and setpoint objects.

ZoneControl:Thermostat

The thermostatic zone control object is used to control a zone to a specified temperature. ZoneControl:Thermostat references a control type schedule and one or more control type objects which in turn reference one or more setpoint schedules. The example at the end of this section illustrates a complete zone thermostat specification including the control type and setpoint schedules.

The control type schedule and the list of control type/name pairs are directly related. The schedule defines the type of control that is to be used throughout the simulation. Valid Control Types are:

- 0 - Uncontrolled (No specification or default)
- 1 - Single Heating Setpoint
- 2 - Single Cooling SetPoint
- 3 - Single Heating/Cooling Setpoint
- 4 - Dual Setpoint (Heating and Cooling) with deadband

Thus, if the schedule referenced in the ZoneControl:Thermostat statement has a control type of 4 for a particular time period, this indicates that during that time period "Dual Setpoint with deadband" control is to be used. The specific "Dual Setpoint (Heating and Cooling) with deadband" control object to be used is specified in the list of control type/name pairs. Then the specific control type objects reference the thermostat setpoint temperature schedule to be used. Because only one control can be specified for each control type in a ZoneControl:Thermostat statement, there are only four pairs possible in a particular ZoneControl:Thermostat type/name list. This is because individual controls can be defined throughout the simulation, thus giving the user a full range of flexibility. Since putting in the name of the control type directly in the schedule would be very cumbersome, the control types are assigned a number which is used in the schedule profile.

Field: Name

Unique identifying name for the thermostat.

Field: Zone or ZoneList Name

Name of the zone or set of zones that is being controlled. When the ZoneList option is used then this thermostat definition is applied to each of the zones in the zone list effecting a global definition for thermostatic control in the zone.

Field: Control Type Schedule Name

Schedule which defines what type of control is active during the simulation. Valid Control Types are:

- 0 - Uncontrolled (No specification or default)
- 1 - Single Heating Setpoint
- 2 - Single Cooling SetPoint
- 3 - Single Heating Cooling Setpoint
- 4 - Dual Setpoint with Deadband (Heating and Cooling)

Each non-zero control type which is used in this schedule must appear in the following fields which list the specific thermostat control objects to be used for this zone.

Field Set (Control Object Type, Control Name)

Up to four pairs of Control Object Type and Control Name may be listed to specify which control objects are used for this zone. This list is not order-dependent, and the position in this list has no impact on the control type schedule. In the control type schedule, a value of 1 always means "Single Heating Setpoint", even if that control type is not first in this list.

Field: Control Object <x>Type

This field specifies the control type to be used for this zone. Available control types are:

```
ThermostatSetpoint:SingleHeating
ThermostatSetpoint:SingleCooling
ThermostatSetpoint:SingleHeatingOrCooling
ThermostatSetpoint:DualSetpoint
```

Field: Control <x> Name

The corresponding control type name. The name is used in an object with the name of the control type and specifies the schedule.

An example of this statement in an IDF is:

```
ZoneControl:Thermostat, Zone 3 Thermostat, NORTH ZONE,
  Zone Control Type Sched,
    DUAL SETPOINT WITH DEADBAND, VAV Setpoints;
```

An example of a global thermostat:

```
ZoneList,AllControlledZones,SPACE1-1,SPACE2-1,SPACE3-1,SPACE4-1,SPACE5-1;

ZoneControl:Thermostat,
  AllControlledZones Thermostat,           !- Name
  AllControlledZones,                      !- Zone Name
  Zone Control Type Sched, !- Control Type Schedule Name
  ThermostatSetpoint:SingleCooling,        !- Control 1 Object Type
  CoolingSetPoint,                         !- Control 1 Name
  ThermostatSetpoint:SingleHeating,         !- Control 2 Object Type
  HeatingSetpoint,                         !- Control 2 Name
  ThermostatSetpoint:DualSetpoint,          !- Control 3 Object Type
  DualSetPoint;                           !- Control 3 Name
```

A complete zone thermostat example showing this statement and all of the objects it must reference is:

```

Zone, Sum, Time Cooling Setpoint Not Met While Occupied Any Zone [hr]

Zone/Sys Sensible Load Predicted[W]

This is the predicted sensible load in W required to meet the current zone thermostat setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active heating and/or cooling setpoints, determines if the zone requires heating or cooling or is in the deadband, and then passes this single load to the equipment. This value is not multiplied by zone or group multipliers.

Zone/Sys Sensible Load to Heating Setpoint Predicted[W]

This is the predicted sensible load in W required to meet the current zone thermostat heating setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is not multiplied by zone or group multipliers.

Zone/Sys Sensible Load to Cooling Setpoint Predicted[W]

This is the predicted sensible load in W required to meet the current zone thermostat cooling setpoint. A positive value indicates a heating load, a negative value indicates a cooling load. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. This value is not multiplied by zone or group multipliers.

Zone/Sys Thermostat Control Type

This is the current zone thermostat control type (0 through 4). This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Heating Setpoint [C]

This is the current zone thermostat heating setpoint in degrees C. If there is no heating thermostat active, then the value will be 0. This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Cooling Setpoint [C]

This is the current zone thermostat cooling setpoint in degrees C. If there is no cooling thermostat active, then the value will be 0. This value is set at each zone timestep. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Time Heating Setpoint Not Met [hr]

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint. See the OutputControl:ReportingTolerances object to change the reporting range from 0.2 degrees C.

Time Heating Setpoint Not Met While Occupied [hr]

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint and when people are present in the zone. To change the reporting range from 0.2 degrees C, see the OutputControl:ReportingTolerances object.

Time Cooling Setpoint Not Met [hr]

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint. See the OutputControl:ReportingTolerances object to change the reporting range from 0.2 degrees C.

Time Cooling Setpoint Not Met While Occupied [hr]

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint and when people are present in the zone. To change the reporting range from 0.2 degrees C, see the OutputControl:ReportingTolerances object.

Time Heating Setpoint Not Met Any Zone [hr]

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint in any one or more zones. See the OutputControl:ReportingTolerances object to change the reporting range from 0.2 degrees C.

Time Heating Setpoint Not Met While Occupied Any Zone [hr]

Hours when the zone temperature is lower than 0.2 (default) degrees C below the heating setpoint and when people are present in any one or more zones. To change the reporting range from 0.2 degrees C, see the OutputControl:ReportingTolerances object.

Time Cooling Setpoint Not Met Any Zone [hr]

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint in any one or more zones. See the OutputControl:ReportingTolerances object to change the reporting range from 0.2 degrees C.

Time Cooling Setpoint Not Met While Occupied Any Zone [hr]

Hours when the zone temperature is greater than 0.2 (default) degrees C above the cooling setpoint and when people are present in any one or more zones. To change the reporting range from 0.2 degrees C, see the OutputControl:ReportingTolerances object.

Time Zone Temperature Oscillating[hr]

Hours when the temperature in the zone is oscillating back and forth. Oscillation is defined as times when the three differences between zone temperatures during successive timesteps are greater in magnitude than 0.15 degrees C and the sign of the differences changes from positive to negative to positive or from negative to positive to negative.

This may indicate a simulation with reduced reliability during the oscillation. Some oscillating hours should be expected in all simulations but excessive oscillations call into question the overall validity of the results. If excessive oscillations are occurring, try reducing the minimum system timestep (see ConvergenceLimits object) and the zone timestep (see the TimeStep object). Reducing these timestep lengths does increase the total computer time needed to complete the simulation. Having the zone timestep and the minimum system timestep the same length of time can also cause more oscillations. What amount of oscillations is considered “excessive” is difficult to quantify. One approach is comparing the number of oscillations to the case with 15 minute zone timesteps (4 per hour) and 1 minute minimum system timesteps. Often this variable is used as an indicator of the validity of the results when trying to decrease the time needed to perform the simulation.

Time Any Zone Temperature Oscillating[hr]

Hours when any zone in the building has oscillations. See Time Zone Temperature Oscillating definition above.

Zone Thermostat Setpoints

The syntax for the current set of four zone thermostat setpoint objects is given below. In each case, the keyword is accompanied by an identifying name and either one or two schedule names (depending on whether the control is a single or dual setpoint control). The schedule defines a temperature setpoint for the control type. The schedule would be defined through the standard schedule syntax described earlier in this document. For an uncontrolled zone no thermostat is specified or necessary.

ThermostatSetpoint:SingleHeating

This would be for a heating only thermostat. The setpoint can be scheduled and varied throughout the simulation but only heating is allowed with this control type.

Field: Name

Unique name for this control type.

Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

ThermostatSetpoint:SingleCooling

This would be for a cooling only thermostat. The setpoint can be scheduled and varied throughout the simulation but only cooling is allowed.

Field: Name

Unique name for this control type.

Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

ThermostatSetpoint:SingleHeatingOrCooling

This would be for heating and cooling thermostat but only heating or cooling can be scheduled at any given time period. The setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Setpoint Temperature Schedule Name

The name of the associated schedule. Values in the schedule are temperatures {C}.

ThermostatSetpoint:DualSetpoint

This would be for heating and cooling thermostat where both a heating and cooling setpoint can be scheduled for any given time period. The setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Heating Setpoint Temperature Schedule Name

The heating temperature schedule. Values in the schedule are temperatures {C}.

Field: Cooling Setpoint Temperature Schedule Name

The cooling temperature schedule. Values in the schedule are temperatures {C}.

Examples of these statements in an IDF are:

```
ThermostatSetpoint:SingleHeating, Heating Setpoint with SB, Heating Setpoints;
ThermostatSetpoint:SingleCooling, Cooling Setpoint with SB, Cooling Setpoints;
ThermostatSetpoint:SingleHeatingOrCooling, Heating Cooling Setpoint Sched, Heating Cooling Setpoints;
ThermostatSetpoint:DualSetpoint, VAV Setpoints, Heating Setpoints, Cooling Setpoints;
```

ZoneControl:Thermostat:OperativeTemperature

This object is used to modify the program's behavior for ZoneControl:Thermostat objects. One input object is used for each thermal zone to indicate if that zone's thermostat control

mode should be overridden to effect operative temperature control rather than traditional air temperature control. Zone Control:Thermostatic and related set point objects also need to be included in the input file. When this object is used, the zone can be controlled by a weighted mixture of radiant and air temperatures (rather than just air temperatures).

This thermostatic operative temperature, T_{OP} , is defined as:

$$T_{OP} = \gamma T_{MRT} + (1 - \gamma) T_{drybulb}$$

where,

γ is the radiative fraction,

T_{MRT} is the mean radiant temperature for the thermal zone, and

$T_{drybulb}$ is the mean zone air temperature.

The radiative fraction γ is selected by the user and can be scheduled to vary during the simulation. A typical value is 0.5. The maximum value needs to be less than 0.9 and the minimum is 0.0. A value of 0.0 is the same as controlling on only zone air temperature. If air velocities are higher than 0.2 m/s, then lower values for radiative fraction might apply. Niu and Burnett (1998) cite International Standard ISO 77300 in recommending the values for this fraction listed in the following table.

Table 28. Radiative Fraction vs Air Velocity (Operative Temperature Control)

Air Velocity (m/s)	< 0.2	0.2 to 0.6	0.6 to 1.0
γ	0.5	0.4	0.3

Reference: J. Niu and J. Burnett. 1998. Integrating Radiant/Operative Temperature Controls into Building Energy Simulations. ASHRAE Transactions Vol. 104. Part 2. page 210. ASHRAE. Atlanta, GA.

Field: Thermostat Name

Name of ZoneControl:Thermostat object defined elsewhere in the input file whose operation is to be modified to effect control based on operative temperature. If the ZoneControl:Thermostat references a ZoneList (set of zones) then, this operative temperature thermostat will be applied to each of those zones. If only a single thermostat/zone is desired, then the name to be put here is <zone name> <Thermostat Name> where the Thermostat name is the thermostat that referenced the set of zones.

Field: Radiative Fraction Input Mode

This field controls whether the input for radiative fraction is a constant value or if it is entered using a schedule. Enter “**Constant**” here to use a fixed radiative fraction defined in the following field. Enter “**Scheduled**” to vary the radiative fraction according to the schedule named in the second field below.

Field: Fixed Radiative Fraction

This is the fraction, γ , of the operative temperature that is due to the mean radiant temperature in the zone. This field is used by the program if the previous field is set to **Constant**.

Field: Radiative Fraction Schedule Name

This field contains the name of a schedule, defined elsewhere, that determines the value for radiative fraction γ during the simulation period. This schedule should have fractional values

from 0.0 to 0.9. When the value of this schedule is 0.0, the controlling will be equivalent to control based only on zone air temperature. This field is used by the program if the Input Mode field is set to **Scheduled**.

Note that by setting the values in this schedule separately for design days, the user can control how operative temperature control is applied during autosizing. (Operative temperature control tends to increase the equipment capacities calculated during sizing.)

An example of this object follows.

```
ZoneControl:Thermostat:OperativeTemperature,
  Zone 1 Thermostat,      !- ZoneControl:Thermostat Name
  Constant,              !- Radiative Fraction Input Mode
  0.5,                  !- Fixed Radiative Fraction
;   !- Radiative Fraction Schedule
```

Zone Control Themostatic Operative Temperature Outputs

Zone,Average,Zone Thermostat Operative Temperature [C]
--

Zone Thermostat Operative Temperature [C]

Operative temperature (OT) is a weighted mixture of Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT), using the current value of Radiative Fraction (RF): $OT = (1-RF)*MAT + RF*MAT$. This output variable does not include the direct effect of high temperature radiant systems. See also Zone Operative Temperature.

ZoneControl:Thermostat:TemperatureAndHumidity

This object is used to modify the behavior of ZoneControl:Thermostat objects (control types ThermostatSetpoint:SingleCooling and ThermostatSetpoint:DualSetpoint only) based on zone air humidity conditions. Specifically, this TemperatureAndHumidity zone control resets the ZoneControl:Thermostat's cooling setpoint temperature downward when the zone air relative humidity exceeds the Dehumidifying Relative Humidity Setpoint defined in this object. The reduced cooling setpoint temperature typically results in longer cooling coil runtimes and additional dehumidification. The rate at which the cooling setpoint temperature is reduced is dictated by the user-specified Overcool Control Ratio. The maximum reduction in cooling setpoint temperature is defined by the user-entered OverCool Range (user choice of a constant value for the entire simulation or a schedule that can define how the overcool range varies over time). For details regarding the calculations, see the EnergyPlus Engineering Reference.

Note: As described above, this ZoneControl:Thermostat:TemperatureAndHumidity control object modifies the cooling setpoint temperature of ZoneControl:Thermostat objects. The ZoneControl:Thermostat:TemperatureAndHumidity object works independently of the ZoneControl:Humidistat object; that is, it does not replace the need for, or coordinate its input fields with, ZoneControl:Humidistat objects that are required for other types of high humidity control (e.g., ZoneControl:Humidistat objects are required for ZoneHVAC:Dehumidifier:DX objects, AirLoopHVAC:Unitary* objects with "CoolReheat" or "MultiMode" dehumidification control types, etc.)

Field: Thermostat Name

Name of ZoneControl:Thermostat object defined elsewhere in the input file whose operation is to be modified to effect temperature control based on zone air humidity conditions. If the ZoneControl:Thermostat references a ZoneList (set of zones), then simply enter the name of the ZoneControl:Thermostat object and this TemperatureAndHumidity thermostat control will be applied to all zones in the ZoneList. If the ZoneControl:Thermostat references a ZoneList but it is desired that only a single zone within the ZoneList be controlled based on TemperatureAndHumidity control, then the name to be put here is <zone name> <Thermostat Name> where the Thermostat Name is the name of the ZoneControl:Thermostat object.

Field: Dehumidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the dehumidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation. This input field is required. This input field has absolutely no relationship or influence on the Dehumidifying Relative Humidity Setpoint Schedule Name optional input field in the ZoneControl:Humidistat object.

Field: Dehumidification Control Type

This input field defines what type of dehumidification control is active during the simulation. Valid control types are None and Overcool. The default is Overcool if this field is left blank. Overcool resets the thermostat's cooling setpoint temperature lower based on the zone air relative humidity level. None means no overcooling (i.e., traditional zone air temperature control based on the associated ZoneControl:Thermostat object [Thermostat Name input field above] will be in effect).

Field: Overcool Range Input Method

This field controls whether the input for the overcool (temperature) range is a constant value or if it is entered using a schedule. Enter "**Constant**" here to use a constant overcool range defined in the "Overcool Constant Range" input field below. Enter "**Scheduled**" to vary the overcool range according to the schedule named in the "Overcool Range Schedule Name" input field below. The default is "**Constant**" if this field is left blank.

Field: Overcool Constant Range

This field specifies a fixed maximum overcool temperature range for cooling setpoint temperature reduction for zone overcool dehumidification in units of deltaC. This field is used if the Overcool Range Input Method is specified as **Constant**. The Overcool dehumidification control type only works with ZoneControl:Thermostat control types “ThermostatSetpoint:SingleCooling” and “ThermostatSetpoint:DualSetpoint”. For “ThermostatSetpoint:DualSetpoint”, the model will use the **smaller** of the Overcool Constant Range input value or the difference between the cooling and heating setpoint temperatures specified in the “ThermostatSetpoint:DualSetpoint” object. The Overcool Constant Range must be greater than or equal to zero with a maximum value of 3°C. A value of 0.0 indicates no zone air overcooling. The default value is 1.7°C (3°F) if this input field is left blank.

Field: Overcool Range Schedule Name

This field contains the name of a schedule, defined elsewhere, that determines the value for the overcool range during the simulation period. This schedule should contain values from 0.0 to <=3.0 (deltaC). When the value of this schedule is 0.0, the zone air temperature control will be based only on zone air dry-bulb temperature (i.e., no zone overcooling). This field is used by the program if the Overcool Range Input Method field is set to **Scheduled**. Overcool dehumidification control type only works with ZoneControl:Thermostat control types “ThermostatSetpoint:SingleCooling” and “ThermostatSetpoint:DualSetpoint”. For “ThermostatSetpoint:DualSetpoint”, the model will use the **smaller** of the Overcool Range values specified in this schedule or the difference between the cooling and heating setpoint temperatures specified in the “ThermostatSetpoint:DualSetpoint” object.

Note that by setting the values in this schedule separately for design days, the user can control how Overcool Dehumidification Control is applied during autosizing. (Overcool dehumidification control tends to increase the cooling equipment capacities calculated during sizing.)

Field: Overcool Control Ratio

The value of this input field is used to adjust the cooling setpoint temperature (established by the associated ZoneControl:Thermostat object) downward based on the difference between the zone air relative humidity level and the Dehumidifying Relative Humidity Setpoint. This input field is only used with Dehumidification Control Type = Overcool. Input values must be greater than or equal to 0.0 %RH/K. The default value is 3.6 if this field is left blank.

An example of this object follows.

```
ZoneControl:Thermostat:TemperatureAndHumidity,
  Zone Thermostat,           !- Thermostat Name
  Seasonal Relative Humidity Sch, !- Dehumidifying Relative Humidity Setpoint Schedule Name
  Overcool,                  !- Dehumidification Control Type
  Constant,                 !- Overcool Range Input Method
  1.7,                      !- Overcool Constant Range {deltaC}
  ,                         !- Overcool Range Schedule Name
  3.0;                     !- Overcool Control Ratio {percent/K}
```

ZoneControl:Humidistat

The humidistat zone control object is used to control a zone to a single relative humidity setpoint schedule, or to dual humidity setpoint schedules (humidifying/ dehumidifying setpoints with deadband). The single setpoint humidistat requires single setpoint input only, and the dual-setpoint humidistat requires inputs of both humidifying and dehumidifying setpoints. The schedules consist of relative humidities, expressed as a percentage (0-100), to be used during the simulation for that zone's moisture prediction calculation. Only one humidistat control statement can be specified for each zone. For a single setpoint humidistat, if the zone relative humidity is below the control relative humidity setpoint and the equipment specified can humidify then that equipment will try and meet the zone's humidification load. The opposite is true if the zone relative humidity is above the control relative humidity

setpoint and the equipment can dehumidify. For a dual setpoint humidistat, if the zone relative humidity is below the **humidifying** relative humidity setpoint and the equipment specified can humidify then that equipment will try and meet the zone's humidification load. The opposite is true if the zone relative humidity is above the **dehumidifying** relative humidity setpoint and the equipment can dehumidify.

If the ZoneControl:Humidistat is used by a furnace or unitary system (Ref. Furnace and Unitary Systems) no other objects are required. The signal from the humidistat is used directly by that component. If the Zone Control:Humidistat object is used to control a Humidifier or used in conjunction with a Controller:WaterCoil object with control variable **TemperatureAndHumidityRatio** or **HumidityRatio**, the following objects are required to determine a setpoint for those components for a single setpoint humidistat:

- SetpointManager:SingleZone:Humidity:Minimum
- SetpointManager:MultiZone:MinimumHumidity:Average
- SetpointManager:MultiZone:MaximumHumidity:Average
- SetpointManager:MultiZone:Humidity:Minimum
- SetpointManager:MultiZone:Humidity:Maximum
- SetpointManager:SingleZone:Humidity:Minimum

For a dual setpoint humidistat, both a maximum humidity setpoint manager object:

- SetpointManager:SingleZone:Humidity:Maximum
- SetpointManager:MultiZone:MaximumHumidity:Average
- SetpointManager:MultiZone:Humidity:Maximum

and a minimum humidity setpoint manager object:

- SetpointManager:SingleZone:Humidity:Minimum
- SetpointManager:MultiZone:MinimumHumidity:Average
- SetpointManager:MultiZone:Humidity:Minimum

are required to determine the setpoints for the corresponding humidification and dehumidification components.

Field: Name

Unique identifying name for the humidistat.

Field: Zone Name

Name of the zone that is being controlled.

Field: Humidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the humidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation.

Note: If only a single setpoint humidistat is desired, then input the single schedule name in the Humidifying Setpoint Schedule Name field (and leave the Dehumidifying Setpoint Schedule Name blank).

Field: Dehumidifying Relative Humidity Setpoint Schedule Name

Name of a schedule that defines the dehumidifying relative humidity setpoint, expressed as a percentage (0-100), for each timestep of the simulation. This field is optional, only used if a dual setpoint humidistat is to be modeled.

An example of this statement in an IDF is:

```

ZoneControl:Humidistat,
Zone 2 Humidistat,           !- Humidistat Name
EAST ZONE,                  !- Zone Name
Min Rel Hum Set Sch,        !- Humidifying Relative Humidity Setpoint SCHEDULE Name
Max Rel Hum Set Sch;        !- Dehumidifying Relative Humidity Setpoint SCHEDULE Name

```

An example schedule for the Zone Control:Humidistat

```

ScheduleTypeLimits,Humidity,0:100,CONTINUOUS;

Schedule:Compact,
Min Rel Hum Set Sch,      !- Name

ZoneControl:Humidistat Outputs

Outputs available from the ZoneControl:Humidistat:

```

HVAC,Average,Zone/Sys Moisture Load Rate Predicted[kgWater/sec]
HVAC,Average,Zone/Sys Moisture Load Rate Predicted to Humidifying Setpoint[kgWater/sec]
HVAC,Average,Zone/Sys Moisture Load Rate Predicted to Dehumidifying Setpoint[kgWater/sec]

```

Zone/Sys Moisture Load Rate Predicted[kgWater/sec]

This is the predicted latent (moisture) load in kg_{water}/s required to meet the current zone humidistat setpoint. A positive value indicates a humidification load, a negative value indicates a dehumidification load. For a dual setpoint humidistat, the value is zero when the controlled zone's relative humidity is between the defined humidifying and dehumidifying setpoints. This moisture load rate is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat setpoints, determines if the zone requires humidification or dehumidification, and then passes this single load to the equipment for the single setpoint humidistat case. This value is not multiplied by zone or group multipliers.

Zone/Sys Moisture Load Rate Predicted to Humidifying Setpoint [kgWater/sec]

This is the predicted latent (moisture) load in kg_{water}/s required to meet the current zone humidistat **humidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires humidification or not, and then passes this load to the equipment for the case of a dual setpoint humidistat (see Zone/Sys Moisture Load Rate Predicted, above, for single setpoint humidistat case). This value is multiplied by zone or group multipliers.

Zone/Sys Moisture Load Rate Predicted to Dehumidifying Setpoint [kgWater/sec]

This is the predicted latent (moisture) load in kg_{water}/s required to meet the current zone humidistat **dehumidifying** setpoint. This is calculated and reported from the Predict step in the Zone Predictor-Corrector module. For nearly all equipment types, the Predictor-Corrector evaluates the active humidistat humidifying setpoints, determines if the zone requires dehumidification or not, and then passes this load to the equipment for a dual setpoint humidistat (see Zone/Sys Moisture Load Rate Predicted, above, for single setpoint humidistat case). This value is multiplied by zone or group multipliers.

ZoneControl:Thermostat:ThermalComfort

The thermal comfort zone control provides a method to control a zone to a dry-bulb temperature setpoint based on a thermal comfort model (e.g. Fanger) and a user-specified thermal comfort setpoint schedule.

This object references a control type schedule and one or more thermal comfort control type objects which in turn reference one or more setpoint schedules. The example at the end of this section illustrates a complete zone thermal comfort control specification including the control type and setpoint schedules. The control type schedule and the list of control type/name pairs are directly related. The schedule defines the type of control that is to be used during for each hour. Valid Control Types are

- 0 – Uncontrolled (No thermal comfort control)
- 1 - Single Thermal Comfort Heating Setpoint:Fanger
- 2 - Single Thermal Comfort Cooling Setpoint:Fanger
- 3 - Single Thermal Comfort Heating Cooling Setpoint:Fanger
- 4 - Dual Thermal Comfort Setpoint with Deadband:Fanger

Thus, if the schedule referenced in the ZoneControl:Thermostat:ThermalComfort statement has a value of 4 for a particular hour, this indicates that during that hour "Dual Thermal Comfort Setpoint with Deadband:Fanger" is to be used. The specific "Dual Thermal Comfort Setpoint with Deadband:Fanger" control object to be used is specified in the list of control type/name pairs. Then the specific control type objects reference the thermal comfort control setpoint schedule to be used. Because only one control can be specified for each control type in a ZoneControl:Thermostat:ThermalComfort statement, there are only four pairs possible in a particular ZoneControl:Thermostat:ThermalComfort type/name list. This is because individual controls can be defined hourly, thus giving the user a full range of flexibility. Since putting in the name of the control type directly in the schedule would be very cumbersome, the control types are assigned a number which is used in the hourly schedule profile.

The ZoneControl:Thermostat:ThermalComfort object can be used alone, or with a ZoneControl:Thermostat object. When both control objects co-exist for a specific zone and the thermal comfort control type value in the thermal comfort control type schedule is non-zero the thermal comfort object will override the value from the zone thermostat object. If the thermal comfort control is specified as "Uncontrolled" (thermal comfort control type value of 0) for a particular period, then control will revert to thermostat control if specified. If the thermal comfort control is specified as "Uncontrolled" for a particular period and thermostat control is not specified in the input, then conditions will float.

This object currently allows only Fanger comfort control (Ref. Thermal Comfort in Engineering Reference). It requires one or more people objects in a specific zone. It also requires inputs of *Fields Activity Level Schedule Name*, *Work Efficiency Schedule Name*, *Clothing Insulation Schedule Name* and *Air Velocity Schedule Name* in the people object(s). When thermal comfort control is used in a zone, the air velocity entered in the Air Velocity Schedule (Ref. People) should be greater than or equal to 0.1 and less than or equal to 0.5 m/s. A warning message will be issued if thermal comfort control is active and the air velocity is outside this range.

This object reads input PMV values from a given PMV setpoint schedule to calculate a dry-bulb temperature setpoint based on the selected thermal comfort model. The dry-bulb temperature setpoint calculation uses zone air humidity ratio at the previous system timestep and surface temperatures at the previous zone timestep, along with other conditions at the current timestep (e.g., activity level, clothing level and air velocity from the PEOPLE object).

Field: Name

Unique identifying name for this thermal comfort control object.

Field: Zone or ZoneList Name

Name of the zone or set of zones that is being controlled. When the ZoneList option is used then this thermostat definition is applied to each of the zones in the zone list effecting a global definition for thermostatic control in the zone.

Field: Averaging Method

This choice field specifies the method for calculating the thermal comfort dry-bulb temperature setpoint for a zone with multiple People objects defined. The available choices are: **SpecificObject**, **ObjectAverage**, and **PeopleAverage**. This field is only used when multiple people objects are defined for this zone. If this field is specified as **PeopleAverage** and the total number of people for all people objects is zero for a particular timestep, the **PeopleAverage** method cannot be applied and the program automatically uses the **ObjectAverage** method for this timestep. The default input is **PeopleAverage**.

Field: Object Name for Specific Object Averaging Method

This choice field specifies the name of the specific People object to be used for calculating comfort control when multiple People objects are defined. Only used if the Averaging Method is specified as "SpecificObject."

Field: Minimum Dry-Bulb Temperature Setpoint

This field specifies the minimum dry-bulb temperature setpoint allowed for this zone. If the dry-bulb temperature calculated by the thermal comfort setpoint model is below this value, then the temperature setpoint will be set to this value. The default value is 0 °C.

Field: Maximum Dry-Bulb Temperature Setpoint

This field specifies the maximum dry-bulb temperature setpoint allowed for this zone. If the dry-bulb temperature calculated by the thermal comfort setpoint model exceeds this value, then the temperature setpoint will be set to this value. The default value is 50 °C.

Note the minimum and maximum temperature setpoint fields are provided to allow the user to bound the temperature control in a specific zone if necessary. These fields are used to provide boundaries for the dry-bulb temperature setpoint calculated at each system timestep when unrealistic inputs have been specified.

Field: Thermal Comfort Control Type Schedule Name

Schedule which defines what type of thermal comfort control is active during each simulation timestep.

Valid Control Types are

- 0 – No thermal comfort control
- 1 - Single Thermal Comfort Heating Setpoint:Fanger
- 2 - Single Thermal Comfort Cooling Setpoint:Fanger
- 3 - Single Thermal Comfort Heating Cooling Setpoint:Fanger
- 4 - Dual Thermal Comfort Setpoint with Deadband:Fanger

Each non-zero control type used in this schedule must appear in the following fields which list the specific thermal comfort control objects to be used for this zone.

Field Set (Thermal Comfort Control Object Type, Thermal Comfort Control Name)

Up to four pairs of Thermal Comfort Control Type and Thermal Comfort Control Type Name fields may be listed to specify which thermal comfort control type objects are used for this zone. This list is not order-dependent, and the position in this list has no impact on the control type schedule. In the control type schedule, a value of 1 always means "Single Thermal Comfort Heating Setpoint:Fanger", even if that control type is not first in this list.

Field: Thermal Comfort Control <x> Object Type

This field specifies the first control type name to be used for this zone. Available control types are:

```
ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating
ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling
ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling
ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint
```

Field: Thermal Comfort Control <x> Name

The unique name for the corresponding thermal comfort control type.

An example of this statement in an IDF is:

```
ZoneControl:Thermostat:ThermalComfort,
  Zone 2 Comfort Control,          !- Thermal Comfort Control Name
  EAST ZONE,                     !- Zone Name
  SpecificObject,                !- Averaging Method for Zones with Multiple People Objects
  EAST ZONE,                     !- Object Name for Specific Object Averaging Method
  12.8,                          !- Minimum dry-bulb temperature setpoint
  40.0,                          !- Maximum dry-bulb temperature setpoint
  Zone Comfort Control Type Sched, !- Thermal Comfort Control Type SCHEDULE Name
  Dual Thermal Comfort Setpoint WITH DEADBAND:Fanger, !- Control Type #1
  Dual Comfort Setpoint;         !- Thermal Comfort Control Type Name #1
```

Global thermal comfort thermostat example:

```

```

ZoneControl:Thermostat:ThermalComfort Outputs

Three outputs are available from the ZoneControl:Thermostat:ThermalComfort object. Two output variables used primarily for the ZoneControl:Thermost object are also described here to explain their meaning when using thermal comfort control.

ZONE CONTROL: THERMAL COMFORT
Zone,Average,Zone/Sys Thermal Comfort Control Type
Zone,Average,Zone/Sys Thermal Comfort Control Fanger Low PMV
Zone,Average,Zone/Sys Thermal Comfort Control Fanger High PMV
ZoneControl:Thermostat
Zone,Average,Zone/Sys Thermostat Heating Setpoint [C]
Zone,Average,Zone/Sys Thermostat Cooling Setpoint [C]

Zone/Sys Thermal Comfort Control Type

This is the current zone thermal comfort control type (0 through 4). This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for

longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermal Comfort Control Fanger Low PMV

This is the current zone thermal comfort low PMV value. Values range between -3 and +3. If there is no heating thermal comfort active, then the value reported will be -999. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermal Comfort Control Fanger High PMV

This is the current zone thermal comfort high PMV value. Values range between -3 and +3. If there is no cooling thermal comfort active, then the value reported will be 999. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Heating Setpoint [C]

The Zone Control:Thermal Comfort object shares the same output variable and overwrites the thermal setpoints defined in object Zone Control:Thermostatic when both objects of Zone Control:Thermostatic and Zone Control:Thermal Comfort co-exist. It outputs the current zone thermal comfort heating setpoint in degrees C when thermal comfort control is active, otherwise this output variable will report the thermostat heating setpoint (Ref. Zone Control:Thermostatic Outputs). If there is no heating thermal comfort active and no thermostat heating setpoint is defined for this zone, this value will be 0. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Zone/Sys Thermostat Cooling Setpoint [C]

This output variable defined in object Zone Control:Thermostatic. The Thermal Comfort object shares the same output variable and overwrites the thermal setpoints defined in object Zone Control:Thermostatic when both objects of Zone Control:Thermostatic and Zone Control:Thermal Comfort co-exist. It outputs the current zone thermal comfort cooling setpoint in degrees C when thermal comfort control is active, otherwise this output variable will report the thermostat cooling setpoint (Ref. Zone Control:Thermostatic Outputs). If there is no cooling thermal comfort active and no thermostat cooling setpoint is defined for this zone, this value will be 0. This value is set at each system timestep and averaged over the reporting interval. Using the averaged value for longer reporting frequencies (hourly, for example) may not be meaningful in some applications.

Thermal Comfort Setpoints

The syntax for the current set (4) of zone thermal comfort control types is given below. In each case, the keyword is accompanied by an identifying name and either one or two schedule names (depending on whether the control type is a single or dual setpoint control). The schedule defines a Predicted Mean Vote (PMV) setpoint for the control type. The schedule would be defined through the standard schedule syntax described earlier in this document. For an uncontrolled thermal comfort zone, no Fanger thermal comfort object is specified or necessary. However, the Fanger thermal comfort output variables, FangerPMV and FangerPPD, are reported for thermal comfort uncontrolled conditions as well (e.g., free floating thermal comfort condition) just like a free floating temperature and humidity ratio. These are indicative of the actual thermal comfort level in uncontrolled thermal comfort zone, and are outputs variables under People objects.

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating

This would be used for heating only thermal comfort control. The PMV setpoint can be scheduled and varied throughout the simulation but only heating is allowed with this control type.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule containing FANGER PMV values.

ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling

This would be used for cooling only thermal comfort control. The PMV setpoint can be scheduled and varied throughout the simulation but only cooling is allowed with this control type.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule, containing FANGER PMV values.

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling

This would be used for heating and cooling thermal comfort control but only heating or cooling can be scheduled at any given time period. The PMV setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Schedule Name

The name of the associated schedule containing FANGER PMV values.

ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint

This would be used for heating and cooling thermal comfort control where both a heating and cooling PMV setpoint can be scheduled for any given time period. The PMV setpoint can be scheduled and varied throughout the simulation for both heating and cooling.

Field: Name

Unique name for this control type.

Field: Fanger Thermal Comfort Heating Schedule Name

The name of the associated schedule containing heating setpoint FANGER PMV values.

Field: Fanger Thermal Comfort Cooling Schedule Name

The name of the associated schedule containing cooling setpoint FANGER PMV values.

An example of this statement in an IDF is:

```

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeating,
  Heating Comfort Setpoint, !- Name
  Heating PMV Setpoints;  !- Setpoint Temperature SCHEDULE Name

ThermostatSetpoint:ThermalComfort:Fanger:SingleCooling,
  Cooling Comfort Setpoint, !- Name
  Cooling PMV Setpoints;  !- Setpoint Temperature SCHEDULE Name

ThermostatSetpoint:ThermalComfort:Fanger:SingleHeatingOrCooling,
  Heating Cooling Comfort Setpoint, !- Name
  Heating Cooling PMV Setpoints;  !- Setpoint Temperature SCHEDULE Name

ThermostatSetpoint:ThermalComfort:Fanger:DualSetpoint,
  Dual Comfort Setpoint,  !- Name
  Heating PMV Setpoints,  !- Fanger Thermal Comfort Heating Setpoint PMV SCHEDULE Name
  Cooling PMV Setpoints;  !- Fanger Thermal Comfort Cooling Setpoint PMV SCHEDULE Name

```

ZoneControl:ContaminantController

The ZoneControl:ContaminantController object is used for any of the following two purposes based on the system outdoor air method specified in the Controller:MechanicalVentilation.

- 1) To control a zone to a specified indoor level of contaminants. When this zone is served by an AirLoopHVAC, the other zones served by the same AirLoopHVAC will have the same specified indoor level, if no objects in the other zones served by the same AirLoop are specified. Currently, the available contaminant controls are carbon dioxide and generic contaminant controls. The specified carbon dioxide setpoint is used to calculate the required outdoor airflow rate through the HVAC system to reach the setpoint. The AirLoopHVAC system outdoor flow rate is realized by the Controller:MechanicalVentilation object with System Outdoor Air Method = IndoorAirQualityProcedure. The specified generic contaminant setpoint is used to calculate the required outdoor airflow rate through the HVAC system to reach the setpoint. The AirLoopHVAC system outdoor flow rate is realized by the Controller:MechanicalVentilation object with System Outdoor Air Method = IndoorAirQualityProcedure-GenericContaminant.
- 2) To specify minimum CO₂ concentration schedule name for a zone. The AirLoopHVAC system outdoor flow rate is realized by the Controller:MechanicalVentilation object with System Outdoor Air Method = ProportionalControl. "Carbon Dioxide Control Availability Schedule Name" determines the availability of "ProportionalControl".

For the first purpose above, when multiple zones are served by an AirLoop, those zones that do not have a contaminant controller object specified in the input data file are automatically assigned a carbon dioxide setpoint. Zone objects entered in the input data file are internally assigned an index number from 1 to n (first defined Zone object = 1, next Zone object defined in the input file = 2, etc.). For zones served by an AirLoop that do not have a contaminant controller specified, the zone's carbon dioxide setpoint will be the same as the zone with the next highest zone index number that has a contaminant controller specified. If a zone with a higher index number and contaminant controller specified does not exist, then the zone with the next lowest zone index number that has a contaminant controller specified will be used. For example, assume an AirLoop serves zones 1 through 5, but one ZoneControl:ContaminantController object is specified for zone 2, a second ZoneControl:ContaminantController object is specified for zone 4, and no ZoneControl:ContaminantController objects are specified for zones 1, 3 and 5. In this case, zone 1 will be assigned the carbon dioxide setpoint schedule that was specified for zone 2, and zones 3 and 5 will be assigned the carbon dioxide setpoint schedule that was specified for zone 4.

Field: Name

Unique identifying name for the ZoneControl:ContaminantController.

Field: Controlled Zone Name

Name of the zone that is being controlled.

Field: Carbon Dioxide Control Availability Schedule Name

This field contains the name of a schedule that determines whether or not the ZoneControl:ContaminantController is available. When the schedule value is zero, the ZoneControl:ContaminantController is bypassed (not available to operate). When the schedule value is greater than zero, the ZoneControl:ContaminantController is available and will be used to calculate the required outdoor airflow rate to reach the carbon dioxide setpoint.

Field: Carbon Dioxide Setpoint Schedule Name

This field contains the name of a schedule that contains the zone carbon dioxide concentration setpoint as a function of time. The units for carbon dioxide setpoint are ppm. The setpoint values in the schedule must be between 0 and 2000 ppm. This field is used when the field "System Outdoor Air Method" = IndoorAirQualityProcedure in the Controller:MechanicalVentilation object.

Field: Minimum Carbon Dioxide Concentration Schedule Name

This field contains the name of a schedule that contains the minimum zone carbon dioxide concentration setpoint as a function of time. The units for carbon dioxide setpoint are ppm. This field is used when the field "System Outdoor Air Method" = ProportionalControl in the Controller:MechanicalVentilation object.

Field: Generic Contaminant Control Availability Schedule Name

This field contains the name of a schedule that determines whether or not the ZoneControl:ContaminantController is available. When the schedule value is zero, the generic contaminant control will not be performed. When the schedule value is greater than zero, the ZoneControl:ContaminantController is available and will be used to calculate the required outdoor airflow rate to reach the generic contaminant setpoint.

Field: Generic Contaminant Setpoint Schedule Name

This field contains the name of a schedule that contains the zone generic contaminant concentration setpoint as a function of time. The units for generic contaminant setpoint are ppm. The setpoint values in the schedule must be between 0 and 1 ppm.

An IDF example is provided below:

```

ZoneControl:ContaminantController,
  CO2 Controller1,          !- Name
  EAST ZONE,                !- Controlled Zone Name
  CO2AvailSchedule,         !- Carbon Dioxide Control Availability Schedule
Name
  CO2SetpointSchedule,      !- Carbon Dioxide Setpoint Schedule Name
  GCAvailSchedule,          !- Generic Contaminant Control Availability
Schedule Name
  GCSetpointSchedule;       !- Generic Contaminant Setpoint Schedule Name

```

ZoneControl:ContaminantController Outputs

The following output variables are available when the ZoneControl:ContaminantController object is specified.

HVAC,Average,Zone/Sys CO2 Load Rate Predicted to Carbon Dioxide Setpoint [kg/s]
HVAC,Average,Zone/Sys Carbon Dioxide Setpoint [ppm]

HVAC,Average,Zone/Sys Generic Contaminant Load Rate Predicted to Generic Contaminant Setpoint [kg/s]
HVAC,Average,Zone/Sys Generic Contaminant Setpoint [ppm]

Zone/Sys CO₂ Load Rate Predicted to Carbon Dioxide Setpoint [kg/sec]

This output is the average predicted outdoor airflow rate in kg/s required to meet the current zone carbon dioxide setpoint for the time step being reported. This value is calculated and reported from the Predict step in the Zone Contaminant Predictor-Corrector module. The calculated outdoor airflow rate will be specified in the Controller:MechanicalVentilation object with System Outdoor Air Method = IndoorAirQualityProcedure to provide enough outdoor ventilation air to keep the zone air carbon dioxide concentration level at or below the setpoint.

Zone/Sys Carbon Dioxide Setpoint [ppm]

This output variable is the average carbon dioxide setpoint value, in parts per million, for the time step being reported.

Zone/Sys Generic Contaminant Load Rate Predicted to Carbon Dioxide Setpoint [kg/sec]

This output is the average predicted outdoor airflow rate in kg/s required to meet the current zone generic contaminant setpoint for the time step being reported. This value is calculated and reported from the Predict step in the Zone Contaminant Predictor-Corrector module. The calculated outdoor airflow rate will be specified in the Controller:MechanicalVentilation object with System Outdoor Air Method = IndoorAirQualityProcedure-GenericContaminant to provide enough outdoor ventilation air to keep the zone air generic contaminant concentration level at or below the setpoint.

Zone/Sys Generic Contaminant Setpoint [ppm]

This output variable is the average generic contaminant setpoint value, in parts per million, for the time step being reported.

Group -- Air Path

AirLoopHVAC:SupplyPath, AirLoopHVAC:ReturnPath

The zone supply and return air paths are used to describe the configuration of the flow path that the supply air takes in moving from the main air handler to the zone terminal units and that the return air takes on leaving the zones and returning to the central return air duct. The air paths consist of a group of components – AirLoopHVAC:ZoneSplitters and AirLoopHVAC:SupplyPlenums for the supply path and AirLoopHVAC:ReturnPlenums and AirLoopHVAC:ZoneMixers for the return path. The connectivity of the paths is established by the components' node connections. There are no branches defined in the zone air path constructs.

For a typical single duct air system there will be one AirLoopHVAC:SupplyPath and one AirLoopHVAC:ReturnPath. A typical dual duct system would have 2 AirLoopHVAC:SupplyPaths – one for the hot air and one for the cold air – and 1 AirLoopHVAC:ReturnPath.

The AirLoopHVAC:SupplyPlenum component provides the capability to have supply air distributed to the conditioned zones through one or more plenum zones such as would occur in an underfloor air distribution system (UFAD). The AirLoopHVAC:ReturnPlenum component allows the program to model return air plenums. Of course plenums are always optional. The simplest AirLoopHVAC:SupplyPath would consist of only an AirLoopHVAC:ZoneSplitter; similarly the simplest return air path consists of a single AirLoopHVAC:ZoneMixer. A UFAD system supply air path might consist of a single AirLoopHVAC:ZoneSplitter connecting to multiple AirLoopHVAC:SupplyPlenums which in turn could each supply one or more conditioned zones. A system with return plenums would have an AirLoopHVAC:ReturnPath in

which the conditioned zones connect to the return plenum inlets and the return plenum's outlets connect to a single AirLoopHVAC:ZoneMixer.

Both the zone supply and return plenums are solved in the heat balance as thermal zones which couple through heat conduction with adjacent zones. Since they are solved as thermal zones the solution scheme involves the zone predictor-corrector technique which will lag the temperature at the system timestep in every zone. See Summary of Predictor-Corrector Procedure in the EnergyPlus Engineering Reference.

Below are the descriptions of the zone supply and return path statements. Note that each statement type has an identifying name, a single inlet/outlet node name, and a list of component type/name pairs. For a single zone being served by an air loop, the inlet to its air distribution unit and the zone return air outlet can be the zone equipment inlet and outlet nodes directly, thus eliminating the need to specify an AirLoopHVAC:SupplyPath and an AirLoopHVAC:ReturnPath.

AirLoopHVAC:SupplyPath

The AirLoopHVAC:SupplyPath lists one or more AirLoopHVAC:ZoneSplitter and AirLoopHVAC:SupplyPlenum components comprising the path. The components are listed in flow order: upstream to downstream and may be in series, parallel, or both. Connectivity is established by means of the individual component inlet and outlet nodes.

Field: Name

Unique name to identify the supply air path..

Field: Supply Air Path Inlet Node Name

The name of an inlet node for the zone equipment half of the air loop. This should be one of the nodes named in the AirLoopHVAC field: Demand Side Inlet Node Names.

Field Set Component Type and Name

The remaining fields are sets of two repeated times: a component type and a name. These pairs of fields define the components on the supply air path.

Field: Component <#> Object Type

Start of the component list for the AirLoopHVAC:SupplyPath. This field should contain either AirLoopHVAC:SupplyPlenum or AirLoopHVAC:ZoneSplitter.

Field: Component <#> Name

Unique name of the AirLoopHVAC:SupplyPlenum or AirLoopHVAC:ZoneSplitter component.

AirLoopHVAC:ReturnPath

The AirLoopHVAC:ReturnPath lists one or more AirLoopHVAC:ZoneMixer and AirLoopHVAC:ReturnPlenum components comprising the path. The components are listed in flow order: upstream to downstream and may be in series, parallel, or both. Connectivity is established by means of the individual component inlet and outlet nodes. At this time there can only be 1 AirLoopHVAC:ZoneMixer in an AirLoopHVAC:ReturnPath.

Field: Name

Unique name to identify the return air path.

Field: Return Air Path Outlet Node Name

The name of the node that is the outlet to the air loop from the AirLoopHVAC:ReturnPath. This should be the same node named in the AirLoopHVAC field: Demand Side Outlet Node Name.

Field Set Component Type and Name

The remaining fields are sets of two repeated times: a component type and a name. These pairs of fields define the components on the return air path.

Field: Component <#> Object Type

Start of the component list for the AirLoopHVAC:ReturnPath. This field should contain either *AirLoopHVAC:ReturnPlenum* or *AirLoopHVAC:ZoneMixer*.

Field: Component <#> Name

Unique name of the AirLoopHVAC:ReturnPlenum or AirLoopHVAC:ZoneMixer.

Example inputs are shown below

```

AirLoopHVAC:SupplyPath,
SupplyAirPath 1,           !- Name
Zone Equip In Node,       !- Supply Air Path Inlet Node Name

AirLoopHVAC:ReturnPath,
ReturnAirPath1,            !- Name
PLENUM-1 Out Node,         !- Return Air Path Outlet Node Name
Zone Return Plenum,        !- Component 1 Object Type
Return-Plenum-1;           !- Component 1 Name

```

AirLoopHVAC:ReturnPlenum

The simple building shown in the figure below consists of a controlled zone and a return plenum zone that is used for the return air. This simple configuration contains a ground floor controlled zone with a window and a return plenum zone which handles the roof load. The return air plenum is a special type of component since there is both a heat balance connection and building description and a system airflow connection that transfers the airflow directly from the controlled zone to the return plenum zone in the system air simulation. The input described in this section is mainly just for the system airflow connections in the HVAC algorithms. In addition the return plenum zone must be fully input as a zone object for the heat balance calculation. The zone description needs to contain the wall descriptions - the interzone ceiling and floor, and for this simple case the roof. All the other attributes of a zone that can be specified in the building description can be used with a return plenum zone if necessary: scheduled loads, windows, etc.

Figure 117. Illustration of Zone Return Plenum

After all the building zone attributes are specified, the AirLoopHVAC:ReturnPlenum object is specified and included as one of the named components in an AirLoopHVAC:ReturnPath.

Field: Name

A unique identifying name identifying the AirLoopHVAC:ReturnPlenum system component.

Field: Zone Name

The zone name specified in the heat balance portion of the input. This piece of input connects the zone return plenum system component to the heat balance data structure.

Field: Zone Node Name

The name of the zone node. The zone node name connects the heat balance data structure to the system airflow data structure through this node. This node name is defined by the user in the field "Zone Air Node Name" in the ZoneHVAC:EquipmentConnections object for the zone named in the previous field.

Field: Outlet Node Name

The name of the return plenum outlet node. For the zone return plenum there is only one outlet node that can be specified.

Field: Induced Air Outlet Node or NodeList Name

The name of an induced air outlet node or the name of a NodeList of such nodes. These nodes are to be used as the secondary inlet air nodes of powered induction terminal units (See **AirTerminal:SingleDuct:SeriesPIU:Reheat** and **AirTerminal:SingleDuct:ParallelPIU:Reheat**).

Field: Inlet <#> Node Name

The name of a plenum inlet node. There is no limit to the number of inlet nodes, and there may be no duplicate inlet node names. (Note that some EnergyPlus editing tools may allow only 500 inlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An IDF example of a zone return plenum component specification:

```

AirLoopHVAC:ReturnPlenum,
  Return-Plenum-1,           !- Name
  PLENUM-1,                 !- Zone Name
  PLENUM-1 Node,            !- Zone Node Name
  PLENUM-1 Out Node,        !- Outlet Node Name
  PLENUM-1 Induced Air Nodes, !- Induced Air Outlet Node or NodeList Name
  SPACE1-1 Out Node,        !- Inlet 1 Node Name
  SPACE2-1 Out Node,        !- Inlet 2 Node Name
  SPACE3-1 Out Node,        !- Inlet 3 Node Name
  SPACE4-1 Out Node,        !- Inlet 4 Node Name
  SPACE5-1 Out Node;        !- Inlet 5 Node Name

NodeList,
  PLENUM-1 Induced Air Nodes,      !- Name
  SPACE1-1 ATU Sec Node,          !- Node 1 Name
  SPACE2-1 ATU Sec Node,          !- Node 2 Name
  SPACE3-1 ATU Sec Node,          !- Node 3 Name
  SPACE4-1 ATU Sec Node;          !- Node 4 Name

```

Below is an example of the AirLoopHVAC:ReturnPath for the simple case shown above.

```

AirLoopHVAC:ReturnPath,
  ReturnAirPath1,             !- Name
  PLENUM-1 Out Node,          !- Return Air Path Outlet Node Name
  AirLoopHVAC:ReturnPlenum,!- Component 1 Object Type
  Return-Plenum-1;            !- Component 1 Name

```

AirLoopHVAC:SupplyPlenum

The building shown in the figure below consists of three controlled zones served by an AirLoopHVAC:SupplyPlenum beneath the floor.

Figure 118. Illustration of AirLoopHVAC:SupplyPlenum

The AirLoopHVAC:SupplyPlenum has a heat balance connection and building description, and a system airflow connection which transfers the airflow from the supply plenum zone to the controlled zones in the system simulation. The input described in this section is mainly just for the system airflow connections in the HVAC algorithms. In addition the supply plenum zone must be fully input in the building zone description. The supply plenum zone description needs to contain the wall descriptions, the interzone ceiling and floor, and the ground

connection. All the other attributes of a zone that can be specified in the building description can be utilized with a supply plenum zone if necessary, i.e. scheduled loads, windows, etc.

After all the building zone attributes are specified, the AirLoopHVAC:SupplyPlenum object is specified and included as one of the named components in an AirLoopHVAC:SupplyPath.

Field: Name

A unique identifying name identifying the AirLoopHVAC:SupplyPlenum system component.

Field: Zone Name

The zone name specified in the heat balance portion of the input. This piece of input connects the AirLoopHVAC:SupplyPlenum system component to the heat balance data structure.

Field: Zone Node Name

The name of the zone node. The zone node name connects the heat balance data structure to the system airflow data structure through this node. This node name is defined by the user in the field "Zone Air Node Name" in the ZoneHVAC:EquipmentConnections object for the zone named in the previous field.

Field: Inlet Node Name

The name of the inlet node to the supply plenum. The AirLoopHVAC:SupplyPlenum component can send air to many outlets, but there is only one inlet.

Field: Outlet <#> Node Name

The name of a plenum outlet node. There is no limit to the number of outlet nodes, and there may be no duplicate outlet node names. (Note that some EnergyPlus editing tools may allow only 500 outlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An IDF example of an AirLoopHVAC:SupplyPlenum component specification:

```
AirLoopHVAC:SupplyPlenum,
  Supply Plenum 1,           ! Name
  SUPPLY PLENUM ZONE,       ! Zone Name
  Supply Plenum 1 Zone Node, ! Zone Node Name
  Zone Equipment Inlet Node, ! Inlet Node Name
  Supply Plenum 1 Outlet Node; ! Outlet 1 Node Name
```

Below is an example of the AirLoopHVAC:SupplyPath for the building shown above.

```
AirLoopHVAC:SupplyPath,
  TermReheatSupplyPath,      ! Name
  Zone Equipment Inlet Node, ! Supply Air Path Inlet Node Name
  AirLoopHVAC:SupplyPlenum,   ! Component 1 Object Type
  Supply Plenum 1,           ! Component 1 Name
  AirLoopHVAC:ZoneSplitter,  ! Component 2 Object Type
  Zone Supply Air Splitter; ! Component 2 Name
```

AirLoopHVAC:ZoneSplitter

The AirLoopHVAC:ZoneSplitter is a component that splits airflow from a single inlet to multiple outlets. This component must be referenced in an AirLoopHVAC:SupplyPath object. The input contains only node connection information.

Field: Name

Unique name for this zone splitter.

Field: Inlet Node Name

The name of the single inlet node going into the splitter.

Field: Outlet <#> Node Name

The name of a splitter outlet node. There is no limit to the number of outlet nodes, and there may be no duplicate outlet node names. (Note that some EnergyPlus editing tools may allow only 500 outlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An example is shown below.

```
AirLoopHVAC:ZoneSplitter,
  Zone Supply Air Splitter,      ! Name
  Zone Equipment Inlet Node,    ! Inlet Node Name
  zone 1 Damper Inlet Node,    ! Outlet 1 Node Name
  Zone 2 Damper Inlet Node,    ! Outlet 2 Node Name
  Zone 3 Damper Inlet Node;   ! Outlet 3 Node Name
```

AirLoopHVAC:ZoneMixer

The AirLoopHVAC:ZoneMixer takes the air from multiple inlets and mixes the streams together to be sent out of a single outlet node. This is a simple process of summing flows and averaging the air properties. This component may be part of an air loop return path or part of an induction terminal unit. When used as a return air mixer, this component must be listed in an AirLoopHVAC:ReturnPath object, and the inlets may be zone return air nodes or AirLoopHVAC:ReturnPlenum outlet nodes. When used in an induction terminal unit (ref. AirTerminal:SingleDuct:SeriesPIU:Reheat, AirTerminal:SingleDuct:ParallelPIU:Reheat, and AirTerminal:SingleDuct:ConstantVolume:FourPipeInduction), one inlet node is the supply (primary) air inlet from the central air handler, and the second inlet node is the induced (secondary) air inlet. These node names should match equivalent node names in the terminal unit.

Field: Name

Unique name for this zone mixer.

Field: Outlet Node Name

The name of the single outlet node leaving the mixer.

Field: Inlet <#> Node Name

The name of a mixer inlet node. There is no limit to the number of inlet nodes, and there may be no duplicate inlet node names. (Note that some EnergyPlus editing tools may allow only 500 inlet node names, but this may be increased by extending the object in the Energy+.idd file.)

An input example is shown below.

```
AirLoopHVAC:ZoneMixer,
  Zone Return Air Mixer,          ! Name

Group -- Non-Zone Equipment

The non-zone equipment group consists of plant objects that connect to the demand side of the plant loop but are not associated with a specific Zone (and do not have their own group). There is currently one non-zone equipment object called LoadProfile:Plant. This object places a scheduled demand load on the plant.

Non-zone equipment allows the option of performing a plant-only EnergyPlus simulation, i.e. without any zones. This can be useful for comparing the performance of various plant configurations or components without the added complexity of a full building description.

LoadProfile:Plant

The LoadProfile:Plant object is used to simulate a scheduled demand profile. This can be useful when the building loads are already known. Demanded load and flow rate are schedules specified in the object definition. The load profile can specify heating and cooling loads. Cooling loads are entered as negative numbers. The actual load met is dependent on the performance of the supply loop components.

The LoadProfile:Plant object must be connected on the demand side of the plant loop. It should be located on a Branch with its control type set to "Active." If desired, multiple LoadProfile:Plant objects can be combined in series and/or parallel.

Field: Name

The unique name of the LoadProfile:Plant object.

Field: Inlet Node Name

The name of the inlet node connection to the plant loop.

This node should be on the demand side.

Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

Field: Load Schedule Name

Reference to the schedule object specifying the load profile [W].

Field: Peak Flow Rate

The peak demanded water flow rate [m^3/s]. This value is multiplied by the flow rate fraction schedule values (below) to determine the actual volumetric flow rate.

Field: Flow Rate Fraction Schedule Name

Reference to the schedule object specifying the flow rate fraction relative to the value in the field Peak Flow Rate (above).

An example of this object follows.

```
LoadProfile:Plant,
  Load Profile 1,           !- Name
  Demand Load Profile 1 Inlet Node,   !- Inlet Node Name
  Demand Load Profile 1 Outlet Node,  !- Outlet Node Name
  Load Profile 1 Load Schedule,      !- Load Schedule Name {w}
  0.003,                      !- Peak Flow Rate {m3/s}
  Load Profile 1 Flow Frac Schedule; !- Flow Rate Fraction Schedule Name
```

LoadProfile:Plant Output

The following output variables and meters are reported for the LoadProfile:Plant object:

HVAC,Average,Plant Load Profile Mass Flow Rate [kg/s]
HVAC,Average,Plant Load Profile Heat Transfer Rate [W]
HVAC,Sum,Plant Load Profile Heat Transfer Energy [J]
Zone,Meter,EnergyTransfer:Facility [J]
Zone,Meter,EnergyTransfer:Plant [J]
Zone,Meter,Miscellaneous:EnergyTransfer [J]

The inlet and outlet node temperatures and mass flow rates can be monitored using the system node output variables:

HVAC,Average,System Node Temp [C]
HVAC,Average,System Node MassFlowRate [kg/s]

Group – Solar Collectors

Solar collectors are thermal devices that convert solar energy into thermal energy by raising the temperature of a circulating heat transfer fluid. The fluid can then be used to heat water for domestic hot water usage or space heating.

In EnergyPlus solar collectors are components that are connected to the plant loop. A solar heating system can be constructed with a combination of solar collectors, pumps, and hot water tanks.

Flat plate solar collectors are defined using two objects: SolarCollector:FlatPlate:Water and SolarCollectorPerformance:FlatPlate. Similarly, Integral-Collector-Storage (ICS) solar collectors are defined using two objects: SolarCollector:IntegralCollectorStorage, and SolarCollectorPerformance:IntegralCollectorStorage. The SolarCollector:FlatPlate:Water and SolarCollector:IntegralCollectorStorage objects describe the plant component connections. These objects also reference SolarCollectorPerformance:FlatPlate and SolarCollectorPerformance:IntegralCollectorStorage performance objects which contain the thermal and optical performance test data for a specific make and model of collector. Parameters are defined separately so that these values can be organized into a reference data set and need only be entered once if for an array of the same type of collectors.

SolarCollector:FlatPlate:Water

The flat-plate solar collector model simulates glazed, unglazed, and tubular (i.e. evacuated tube) collectors. The SolarCollector:FlatPlate:Water object represents a single collector module connected to the plant loop. The thermal and optical properties of the collector module are taken from the referenced SolarCollectorPerformance:FlatPlate object. A surface or shading object defines the collector tilt, azimuth, and gross area. The collector surface participates normally in all shading calculations if the "FullExterior," "FullInteriorAndExterior," "FullExteriorWithReflections", or "FullInteriorAndExteriorWithReflections" flags are set in the Solar Distribution field of the Building object. Inlet and outlet nodes are specified for plant connections on the demand side of the plant loop.

Field: Name

The unique name of the SolarCollector:FlatPlate:Water object.

Field: Solar Collector Performance Name

Reference name of a SolarCollectorPerformance:FlatPlate object that defines the thermal and optical properties of the collector.

Field: Surface Name

Reference to one of the many different types of surfaces such as the BuildingSurface:Detailed or the Shading:Zone:Detailed objects. The surface named here is used to define the solar collector tilt, azimuth, and gross area.

Field: Inlet Node Name

The name of the inlet node connection to the plant loop.

Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

Field: Maximum Flow Rate

The maximum flow rate [m^3/s] allowed through the collector. This field is optional. If not specified, the collector will allow as much flow as the rest of the plant can deliver.

An example follows.

```

SolarCollector:FlatPlate:Water,
  Collector 1,           !- Name
  ACR Solar International Fireball 2001, !- Solar Collector Performance Name
  Collector Surface,      !- Surface Name
  Collector Inlet Node,   !- Inlet Node Name
  Collector Outlet Node, !- Outlet Node Name
  0.00005;               !- Maximum Flow Rate (m3/s)

```

SolarCollector:FlatPlate:Water Output

The following output variables are reported for the SolarCollector:FlatPlate:Water object:

```

HVAC,Average,Solar Collector Incident Angle Modifier []
HVAC,Average,Solar Collector Efficiency []
HVAC,Average,Solar Collector Heat Transfer Rate [W]
HVAC,Average,Solar Collector Heat Gain Rate [W]
HVAC,Average,Solar Collector Heat Loss Rate [W]
HVAC,Sum,Solar Collector Heat Transfer Energy [J]

```

Solar Collector Incident Angle Modifier []

The incident angle modifier is an important intermediate value used in the SRCC calculation of solar collector performance. The value reported here is the combined result for the current time that includes incident angles of beam solar, diffuse solar from sky, and diffuse solar from ground.

Solar Collector Efficiency []

The overall collector efficiency. This is the ratio of collected energy and the incident solar energy. The efficiency can be greater than 1 at times when the outdoor air temperature is warm enough.

Solar Collector Heat Transfer Rate [W]

Solar Collector Heat Transfer Energy [J]

These are the overall rate (in W) and amount of energy (in J) transferred to the collector's circulating fluid. Positive values indicate heating of the fluid while negative values indicate cooling of the fluid.

Solar Collector Heat Gain Rate [W]

This is the overall rate of heat addition to the collector's circulating fluid in Watts. Values are always positive or zero. If the fluid is actually cooled then the value is zero.

Solar Collector Heat Loss Rate [W]

This is the overall rate of heat loss from the collector's circulating fluid in Watts. Values are always positive or zero. If the fluid is actually heated then the value is zero.

In addition, several surface variables are also relevant for the collector's surface object (BuildingSurface:Detailed or Shading:Zone:Detailed):

```

Zone,Average,Surface Ext Sunlit Area [m2]
Zone,Average,Surface Ext Sunlit Fraction []
Zone,Average,Surface Ext Solar Incident [W/m2]
Zone,Average,Surface Ext Solar Beam Incident [W/m2]
Zone,Average,Surface Ext Solar Sky Diffuse Incident [W/m2]
Zone,Average,Surface Ext Solar Ground Diffuse Incident [W/m2]
Zone,Average,Surface Ext Solar Beam Cosine Of Incidence Angle []

```

The temperatures at the inlet and outlet nodes and the collector mass flow rate can be monitored using the system node output variables:

```
HVAC,Average,System Node Temp[C]
```

HVAC,Average, System Node MassFlowRate[kg/s]
--

SolarCollectorPerformance:FlatPlate

The SolarCollectorPerformance:FlatPlate object contains the thermal and optical performance parameters for a single collector module. These parameters are based on the testing methodologies described in ASHRAE Standards 93 and 96. The Solar Rating and Certification Corporation (SRCC) applies these standards in their rating procedures of solar collectors. The ratings for commercially available collectors in North America are published in the *Directory of SRCC Certified Solar Collector Ratings*. The SRCC database has also been converted into an EnergyPlus data set of SolarCollectorPerformance:FlatPlate objects that is included with the program (see SolarCollectors.idf in the DataSets folder).

The coefficients for the energy conversion efficiency and incident angle modifier allow first order (linear) or second order (quadratic) correlations. To use a first order correlation, the second order coefficient must be left blank or set to zero.

In order for the model to work correctly, the test conditions for which the performance coefficients were measured must be specified in the fields: *Test Fluid*, *Test Volumetric Flow Rate*, and *Test Correlation Type*. Currently, only water is allowed as the *Test Fluid*.

For more detailed information about the performance coefficients, see the *EnergyPlus Engineering Reference Document*.

Field: Name

The unique name of the SolarCollectorPerformance:FlatPlate object.

Field: Gross Area

The gross area of the collector module [m^2]. This value is mainly for reference. The area of the associated collector surface object is used in all calculations.

Field: Test Fluid

The fluid that was used in the testing procedure that resulted in the thermal and optical performance coefficients below. Currently only "Water" is allowed. This is the fluid during the collector testing, not the fluid used during a particular EnergyPlus run.

Field: Test Flow Rate

The volumetric flow rate during testing [m^3/s]. If the value is available as flow rate per unit area, it is recommended to multiply by the *Gross Area* of the collector module, not the net aperture area.

Field: Test Correlation Type

This field specifies type of temperature used to develop the correlation equations. The testing procedure is based on an experimental correlation using either "Inlet," "Average," or "Outlet" temperature. Enter one of these choices. The ASHRAE Standards 93 and 96 always use Inlet temperature.

Field: Coefficient 1 of Efficiency Equation

First coefficient of efficiency equation for energy conversion [dimensionless]. This is the Y-intercept term.

Field: Coefficient 2 of Efficiency Equation

Second coefficient of efficiency equation for energy conversion [$\text{W}/\text{m}^2\text{-deltaC}$]. This is the first-order term.

Field: Coefficient 3 of Efficiency Equation

Third coefficient of efficiency equation for energy conversion [$\text{W}/\text{m}^2 \cdot \Delta C^2$]. This field is optional. This is the second-order term. If left blank or set to zero, a first-order linear correlation is used.

Field: Coefficient 2 of Incident Angle Modifier

Second coefficient of the incident angle modifier equation. This is the first-order term. (There is no *Coefficient 1 of Incident Angle Modifier* because that number is always 1.0.)

Field: Coefficient 3 of Incident Angle Modifier

Third coefficient of the incident angle modifier equation. This is the second-order term. This field is optional. If left blank or set to zero, a first order linear correlation is used.

An example of this object follows.

```

SolarCollectorPerformance:FlatPlate Output

This object does not generate any output; see SolarCollector:FlatPlate:Water Output

SolarCollector:IntegralCollectorStorage

The Integral-Collector-Storage (ICS) solar collector model simulates glazed collectors with integral storage unit. The SolarCollector:IntegralCollectorStorage object represents a single collector module connected to the plant loop. The thermal and optical properties of the collector module are calculated from inputs in SolarCollectorPerformance:IntegralCollectorStorage object. A surface or shading object defines the collector tilt, and azimuth. The collector surface participates normally in all shading calculations if the "FullExterior," "FullInteriorAndExterior," "FullExteriorWithReflections", or "FullInteriorAndExteriorWithReflections" flags are set in the Solar Distribution field of the Building object. Inlet and outlet nodes are specified for plant connections on the demand side of the plant loop. The SurfaceProperty:ExteriorNaturalVentedCavity, object is required to describe the surface properties, the characteristics of the cavity and opening for natural ventilation if OtherSideConditionsModel is specified as the collector bottom surface outside boundary condition type.

Field: Name

The unique name of the SolarCollector:IntegralCollectorStorage object.

Field: Solar Collector Performance Name

Reference name of a SolarCollectorPerformance:IntegralCollectorStorage object that defines the thermal and optical properties of the collector.

Field: Surface Name

Reference to one of the many different types of surfaces such as the BuildingSurface:Detailed or the Shading:Zone:Detailed objects. The surface named here is

used to define the solar collector tilt, and azimuth. The collector shades the surface it is mounted on and hence impacts the surface heat balance.

Field: Bottom surface Boundary Conditions Type

This field contains the type of boundary conditions applicable to the ICS collector bottom surface. Allowed boundary condition types are: AmbientAir and OtherSideConditionsModel. If the other side conditions model is selected, specify the name of the SurfaceProperty:OtherSideConditionsModel object in the next input field, otherwise, leave the next input field blank. The AmbientAir boundary condition uses outdoor air temperature as boundary condition, hence the subsurface is assumed to be exposed to the sun and wind.

Field: Other Side Conditions Model Name

This field contains the name of a SurfaceProperty:OtherSideConditionsModel object declared elsewhere in the input file. This will connect the collector to the exterior boundary conditions for the underlying heat transfer surface specified above..

Field: Inlet Node Name

The name of the inlet node connection to the plant loop.

Field: Outlet Node Name

The name of the outlet node connection to the plant loop.

Field: Maximum Flow Rate

The maximum flow rate [m³/s] allowed through the collector. This field is optional. If not specified, the collector will allow as much flow as the rest of the plant can deliver.

An example follows.

```
SolarCollector:IntegralCollectorStorage,
  Collector 1,                               !- Name

  0.00005;                                 !- Maximum Flow Rate (m3/s)
```

SolarCollectorPerformance:IntegralCollectorStorage

The SolarCollectorPerformance:IntegralCollectorStorage object contains the thermal and optical performance parameters for a single collector module. The transmittance-absorptance product of the absorber and cover system is determined from optical properties specified. For more detailed information about the calculation procedure, see the *EnergyPlus Engineering Reference Document*.

Field: Name

The unique name of the SolarCollectorPerformance:IntegralCollectorStorage object.

Field: ICS Collector Type

This input field is the ICS collector type. Currently only RectangularTank type is allowed.

Field: Gross Area

This input field is the gross area of the collector module in m². This gross area is used in the energy balance equations.

Field: Collector Water Volume

This input field is the volume of water in the solar collector in m³.

Field: Bottom Heat Loss Conductance

This input field is the collector bottom heat loss conductance in W/m²K. This value is calculated from thermal conductivity and thickness of the bottom insulation.

Field: Side Heat Loss Conductance

This input field is the collector side heat loss conductance in W/m²K. This value is calculated from thermal conductivity and thickness of the side insulation.

Field: Collector Aspect Ratio

This input field is the ratio of the short side (width) of the collector to the long side (length) of the collector. This value is used only for calculating the collector side area along with the collector side height specified in the next input field. This ratio is less or equal to 1.0.

Field: Collector Side Height

This input field is height of collector side in m. This height is used to estimate the collector side area for heat loss calculations along with heat loss coefficient specified in the input field above.

Field: Thermal Mass of Absorber Plate

This input field is thermal-mass of the absorber plate per unit area of the collector in [J/m²·K]. This input value multiplied by the absorber gross area determines the thermal mass of the absorber plate. It is estimated from the specific heat, density and average thickness of the absorber plate. If zero is specified then the absorber plate energy balance reduces to steady state form.

Field: Number of Covers

Number of transparent collector covers. Common practice is to use two covers: glass as the outer cover and Teflon as the inner cover. If single cover is specified leave the inner cover optical and thermal properties input fields blank.

Field: Cover Spacing

This input field provides the spacing between the two transparent covers, and the spacing between the inner cover and the absorber plate in m. Default value is 0.05m.

Field: Refractive Index of Outer Cover

This is the average Refractive index for solar spectrum range of the outer transparent cover material. Glass is used as the outer cover. Average refractive index value for non-absorbing glass used in solar collectors over solar spectrum range is 1.526.

Field: Extinction Coefficient Times Thickness of Outer Cover

This input field is the product of the extinction coefficient and the thickness of the out cover material. The extinction coefficient for glass types approximately varies from 4m⁻¹ to 32 m⁻¹. The extinction coefficient for low-iron glass, which is the default outer cover material, is 15 m⁻¹. The default value for extinction coefficient times thickness (KL) is 0.045 (=15.0 x0.003), which is the product of the default extinction coefficient of 15m⁻¹ and 3.0mm thick glass.

Field: Emissivity of Outer Cover

This input field value is thermal emissivity of the outer collector cover. The default value assumes low-iron glass with thermal emissivity of 0.88.

Field: Refractive Index of Inner Cover

This input field is the average Refractive index of the inner transparent cover of the collector. Commonly Teflon (PolytetraFluoroethylene) is used as the inner cover. The average refractive index value over the solar spectrum range for Teflon is 1.37.

Field: Extinction Coefficient Times Thickness of Inner Cover

This input field is the product of the extinction coefficient (K) and the thickness (L) of the inner cover material. The inner cover material is more transparent than the out cover, very thin and hence their thickness can be assumed to be negligible. The default value for extinction coefficient times thickness (KL) is 0.008 (=40.0x0.0002), which is the product of extinction coefficient of 40m⁻¹ and a thickness of 0.2mm.

Field: Emissivity of Inner Cover

This input field value is thermal emissivity of the inner transparent collector cover. The default value assumes plastic sheet with thermal emissivity of 0.30. This value is used in the thermal analysis only.

Field: Absorptance of Absorber Plate

This input field is shortwave or solar absorptance of the absorber plate. The default value is 0.96.

Field: Emissivity of Absorber Plate

This input field value is thermal emissivity of the absorber plate. Default value is 0.30. This input value is used in the thermal analysis only.

An example follows.

SolarCollector:IntegralCollectorStorage Outputs

The following output variables are reported for the SolarCollector:IntegralCollectorStorage object:

```
HVAC,Average,ICS Solar Collector Entering Water Temperature[C]
HVAC,Average,ICS Solar Collector Leaving Water Temperature[C]
HVAC,Average,ICS Solar Collector Stored Water Temperature[C]
HVAC,Average,ICS Solar Collector Absorber Plate Temperature [C]
HVAC,Average,ICS Overall Top Heat Loss Coefficient [W/m2C]
HVAC,Average,ICS Solar Collector Efficiency []
HVAC,Average,ICS Solar Collector Stored Heat Rate [W]
HVAC,Sum,ICS Solar Collector Stored Heat Energy [J]
HVAC,Average,ICS Solar Collector Heat Transfer Rate [W]
HVAC,Sum,ICS Solar Collector Heat Transfer Energy [J]
HVAC,Average,ICS Solar Collector Skin Heat Loss Rate [W]
HVAC,Sum, ICS Solar Collector Skin Heat Loss Energy [J]
HVAC,Average,ICS Solar Collector Transmittance-Absorptance Product []
```

ICS Solar Collector Entering Water Temperature[C]

This output variable is the ICS collector entering water temperature at a given time step in degree Celsius.

ICS Solar Collector Leaving Water Temperature[C]

This output variable is the ICS collector leaving water temperature at a given time step in degree Celsius.

ICS Solar Collector Stored Water Temperature[C]

This output variable is the ICS collector stored water average temperature at a given time steps in degree Celsius. This temperature is the same as the collector ICS collector leaving water temperature.

ICS Solar Collector Absorber Plate Temperature [C]

This output variable is the ICS collector absorber plate average temperature at a given time steps in degree Celsius.

ICS Solar Collector Efficiency []

This output variable is the instantaneous thermal efficiency of the ICS solar collector in per cent. This value is determined from net useful energy collected and the total incident solar radiation for each time step. The net useful energy collected is the sum of the energy stored in the collector and net useful energy delivered.

ICS Solar Collector Stored Heat Rate [W]***ICS Solar Collector Stored Heat Energy [J]***

These output variables are the instantaneous rate of change of the energy and the change in energy of the water in the ICS solar collector in Watts, and Joules, respectively.

ICS Solar Collector Skin Heat Loss Rate [W]***ICS Solar Collector Skin Heat Loss Energy [J]***

These output variables are the instantaneous skin heat loss rate and the heat loss energy of the ICS solar collector for each time steps in Watts, and Joules respectively. The skin heat loss rate is the sum of the heat losses through the top, bottom and sides of the collector surfaces. This value is mostly negative, but can have a positive value (heat gain) when the outdoor air temperature is warmer than the collector.

ICS Solar Collector Heat Transfer Rate [W]***ICS Solar Collector Heat Transfer Energy [J]***

This output variable is the heat rate and Energy transferred from the ICS collector to the collector loop fluid (water) in Watts and Joule, respectively. This value is determined from the collector water mass flow rate, specific heat of water and the temperature difference between the collector water outlet and inlet nodes at each time step. The value is positive when the fluid is heated or negative when cooled.

ICS Solar Collector Transmittance-Absorptance Product []

This output variable is the transmittance-absorptance product of the covers and absorber system of the ICS solar collector. This value ranges from 0.0 to less than 1.0.

ICS Overall Top Heat Loss Coefficient [W/m²-C]

This output variable is the overall heat loss coefficient from the absorber plate to the ambient air calculated for each time step.

SolarCollector:FlatPlate:PhotovoltaicThermal

This object is used to model hybrid photovoltaic-thermal (PVT) solar collectors that convert incident solar energy into both electricity and useful thermal energy. This object describes the PVT solar collector by referencing other objects that provide more detail or connections to other parts of the EnergyPlus model.

The PVT solar collectors need to be connected to either an HVAC air system or a plant loop for collected thermal energy to be utilized. The input field for the type of thermal working fluid informs the program how the PVT collector is expected to be connected. If the the working fluid is air, then the PVT collectors are modeled as a ventilation air pretreatment component and connected to an outdoor air system. If the working fluid is water, then the PVT collectors are modeled as a hot water solar collector and are connected to a plant loop with a water thermal storage tank.

Field: Name

This field should contain a unique name chosen by the user to identify a specific PVT collector in the building model.

Field: Surface Name

This field is the user-defined name of a surface object (defined elsewhere) to which the PVT module is attached. These can be any type of building surface that is exposed to the exterior environment. The model uses the named surface's geometry for the PVT solar collector.

Field: Photovoltaic-Thermal Model Performance Name

This field is the user-defined name of an object (defined elsewhere) that provides the performance details of the PVT module. This should be the name of a SolarCollectorPerformance:PhotovoltaicThermal:Simple object. Multiple different SolarCollector:FlatPlate:PhotovoltaicThermal objects can reference the same object that provides performance details.

Field: Photovoltaic Generator Name

This field is the user-defined name of a Generator:Photovoltaic object (defined elsewhere) that will be used to model the solar electric portion of the PVT solar collector. The PVT models make any adjustments needed to model PV performance in the context of the PVT collector.

Field: Thermal Working Fluid Type

This field is the user's choice for the type of fluid used to collect thermal energy. PVT solar collectors can capture thermal energy in either air or water streams. The choices available for this field are "Water" or "Air." If the choice is "Air" then the PVT collector needs to be connected to an HVAC air system loop. The PVT collector should be situated as the first component on an outdoor air inlet stream. If the choice is "Water" then the PVT collector needs to be connected to a Plant water system loop. The connections are made via node names which are defined in the following fields, depending on the working fluid type.

Field: Water Inlet Node Name

This field is the name of Plant loop node that serves as the inlet to the PVT collector. This field is only used if the Thermal Working Fluid Type is set to "Plant/Water."

Field: Water Outlet Node Name

This field is the name of a plant loop node that seves as the outlet from the PVT collector. This field is only used if the Thermal Working Fluid Type is set to "Plant/Water."

Field: Air Inlet Node Name

This field is the name of HVAC air loop node that serves as the inlet to the PVT collector. This field is only used if the Thermal Working Fluid Type is set to "HVAC/Air."

Field: Air Outlet Node Name

This field is the name of HVAC air loop node that serves as the outlet from the PVT collector. This field is only used if the Thermal Working Fluid Type is set to "HVAC/Air."

Field: Design Flow Rate

This field is used to describe the nominal volume flow rate of the thermal working fluid. The units are m³/s. The volume flow rate is autosizable.

An example of this object follows.

```

SolarCollector:FlatPlate:PhotovoltaicThermal Outputs

The output variables that are available for flat plate PVT include the following.

```
HVAC,Average,Generator Thermal Power Produced [W]
HVAC,Sum,Generator Thermal Energy Produced [J]
HVAC,Average,PVT Bypass Status []
HVAC,Average,PVT Working Fluid Inlet Temperature [C]
HVAC,Average,PVT Working Fluid Outlet Temperature [C]
HVAC,Average,PVT Working Fluid Mass Flow Rate [kg/s]
```

Generator Thermal Power Produced [W]**Generator Thermal Energy Produced [J]**

These outputs are the thermal energy and power produced by the PVT collector. PVT collectors are a type of cogenerator, producing both electrical and thermal power and these variables report the thermal portion in the same manner as other fuel-based cogenerators. The thermal energy is placed on "HeatProduced" meter and is attributed to 'SolarWater' or 'SolarAir' depending on the type of working fluid. The generator thermal production is also reported at the load center level.

PVT Bypass Status []

This output variable indicates the status a bypass damper. It is only available for air-based PVT. There are no dimensions and the range is between 0.0 and 1.0. If the value is 0.0, then there is no bypassing and all the working fluid goes through the collector. If the value is 1.0, then there is complete bypassing and all the working fluid goes around the collector. If the value is between 0.0 and 1.0, then the model is effectively mixing bypass and collector streams to target a temperature setpoint placed on the outlet node.

PVT Working Fluid Inlet Temperature [C]

This report is the inlet temperature of the working fluid that enters the PVT collector

PVT Working Fluid Outlet Temperature [C]

This report is the outlet temperature of the working fluid that leaves the PVT collector

PVT Working Fluid Mass Flow Rate [kg/s]

This report is the mass flow rate of the working fluid through the PVT collector. This is the overall mass flow rate, portions of the flow may be internally bypassed around the collector itself for control modulation.

SolarCollectorPerformance:PhotovoltaicThermal:Simple

This object is used to provide performance details for the simple PVT model. This is a simple user-defined efficiency model. Thermal conversion efficiency is a constant or scheduled value. There are no output variable for this object, reporting is done by the parent PVT object.

Field: Name

This field is the unique name for this object.

Field: Fraction of Surface Area with Active Thermal Collector

This field is the fraction of the surface area that is active. It should be a decimal fraction between 0.0 and 1.0. The area of the PVT's surface will be multiplied by this fraction to determine the active area of the PVT collector(s).

Field: Thermal Conversion Efficiency Input Mode Type

This field is used to determine how the thermal efficiency is input. There are two choices, "Fixed" or "Scheduled." If this field is set to Fixed, then a constant value for thermal efficiency will be used (set in next field). If this field is set to Scheduled, then the thermal efficiency values are defined in a schedule.

Field: Value for Thermal Conversion Efficiency if Fixed

This field is used to provide a value for the efficiency with which solar energy is collected in the working fluid. This field is only used if the input mode is set to "Fixed" in the previous field. Efficiency is defined as the thermal energy collected divided by the incident solar radiation. The value should be between 0.0 and 1.0. The user should be careful that the thermal efficiency and the electrical efficiency be consistent with each other because the overall efficiency of the PVT collector is the combination of both thermal and electrical.

Field: Name of Schedule for Thermal Conversion Efficiency

This field is used for the name of a schedule that provides values for the efficiency with which solar energy is collected in the working fluid. This field is only used if the input mode is set to "Scheduled" in the field above. Efficiency is defined as the thermal energy collected divided by the incident solar radiation. The values in the named schedule should be between 0.0 and 1.0. The user should be careful that the thermal efficiency and the electrical efficiency be consistent with each other because the overall efficiency of the PVT collector is the combination of both thermal and electrical.

Field: Front Surface Emittance

This field is used to describe an average value for the total hemispherical emittance of the collector's front face exposed to the sky. This is used to model cooling applications where the PVT collectors are operated at night to cool the working fluid.

An example input object follows.

```

```

Solar Collector Heating System Plant Connections

This section provides an overview of how to model solar heating systems. A solar heating system can be constructed using a combination of solar collectors, pumps, water tanks and water heaters. The solar collector must be connected on the demand side of the plant loop. Multiple collector modules can be combined in series and parallel using the normal plant connection rules. The supply side of the plant loop should contain a water heater with the solar collector loop connecting to the *Source Side Inlet* and *Source Side Outlet* nodes. As usual, the pump must be the first component on the supply side.

If the solar heating system is for domestic hot water (or service water heating) usage only, the field *Use Flow Rate Fraction Schedule Name* of the WaterHeater:Mixed object can be used to avoid additional plant connections. If the system has more complicated hot water requirements or if the system is for space heating, the *Use Side Inlet* and *Use Side Outlet* nodes must be connected to another plant loop to serve zone and non-zone equipment. (See the WaterHeater:Mixed object documentation for more information.)

Figure 119. Solar Collector Plant Loop Connection Diagram

NOTE: The EnergyPlus plant simulation requires the pump to be the first component on the supply side. This may be different from the way the solar heating system is actually configured. This should not affect the validity of the simulation results.

In order to realize energy savings with a solar heating system, it is best to use a two-tank system with a storage tank and auxiliary water heater. The storage tank gathers heat directly from the solar collectors and stores it for later use. The storage tank is modeled using a WaterHeater:Mixed object with the *Heater Maximum Capacity* set to zero. The auxiliary water heater is positioned downstream of the storage tank on the supply side of the main plant

loop. The auxiliary water heater, or booster water heater, provides additional heat if the storage tank water is not hot enough. The auxiliary water heater can be modeled as an instantaneous/tankless water heater or as a standard tanked water heater with heating source (see WaterHeater:Mixed).

Figure 120. Two-Tank Solar Heating System Connection Diagram

Another strategy to consider for solar heating systems is to allow the storage tank to reach a much higher temperature than necessary for the end use. This allows the tank to store more energy from the solar collectors, when it is available. However, for applications such as domestic hot water, it is undesirable and unsafe to supply excessive hot water temperatures at the point of demand. To take advantage of higher storage temperatures, yet still avoid scalding temperatures at the faucet, the hot water leaving the storage tank can be tempered with cold water using a three-way valve to achieve the target temperature. See the TemperingValve object documentation for more details.

A complete two-tank solar heating system with tempering valve is shown below.

Figure 121. Two-Tank Solar Heating System with Tempering Valve

Solar Heating System Control

There are several options for controlling a solar heating system in EnergyPlus. Since the solar collectors request a constant flow demand based on their *Maximum Flow Rate*, the limiting factor is actually the flow rate determined by the loop pump. Therefore the entire system can be controlled using the *Pump Flow Rate Schedule* of the pump. If the schedule is omitted, the pump and system will run all the time (without any other controls specified). This is usually not the best way to operate a solar heating system.

To better control the collector loop, a differential thermostat can be used to compare the temperature in the water heater to the temperature in the collector so that the pump is only turned on when there is a useful heat gain. The differential thermostat is simulated using the AvailabilityManager:DifferentialThermostat object. For a typical system, the *Hot Node Name* field refers to an outlet node of one of the collector modules. The *Cold Node Name* field refers to the *Source Side Outlet* node, i.e. the cold storage water leaving the water heater. The fields *Temperature Difference On Limit* and *Temperature Difference Off Limit* are usually 8 –12 C and 1 – 3 C respectively. If the two temperature differences are too close, it is possible for the system to turn on and off rapidly without much useful heat gain. This can also

occur if the flow rate through the collector is too high. Without flow the fluid in the collector heats up more quickly; when high flow is turned on, all of the hot fluid is removed and the temperature drops, forcing the system off again.

Another control method is to use a photovoltaic panel to power the pump. The system begins pumping when there is enough solar radiation to operate the pump. This is not yet implemented in EnergyPlus.

Freeze Prevention

In climates with a cold season, the solar heating system must be designed to avoid the risk of fluid freezing in the solar collector or exposed pipes and causing damage. This is not a problem if air is the heat transfer fluid. With water, however, there are several strategies that can minimize the risk.

Seasonal schedule. The simplest strategy is to not use the system during the cold season. This is a hassle because it requires the collector to be manually drained of all fluid. The benefits of the solar heating system are also lost during this time. This can be simulated in EnergyPlus with the appropriate pump schedule for the collector system.

Antifreeze. The freezing point of the liquid is decreased by adding antifreeze to the water or using a different heat transfer liquid with a lower freezing point. This cannot yet be simulated in EnergyPlus because only pure water is currently allowed in plant loops.

Drain-back system. This strategy automatically empties the collector when the pump is not running. This scenario is modeled by default in EnergyPlus, although the extra pump energy required to start the system is not taken into account.

Recirculation system. This strategy automatically recirculates warm liquid from the storage tank back through the collector to maintain the system above the freezing point. There are system losses using this method. This can be simulated in EnergyPlus by using AvailabilityManager:LowTemperatureTurnOn to force the system to turn on when the outdoor air temperature or collector outlet temperature falls below a specified minimum.

Additional Controls

In addition to freeze prevention, it is also necessary to prevent the system from becoming too hot. This is usually a safety issue for the water heater. For this case it is important to have a high temperature cutoff to stop the pump before damaging the water heater. This is accomplished with a AvailabilityManager:HighTemperatureTurnOff.

System Availability Manager List Example

To use the availability managers for the control cases described above, a AvailabilityManagerAssignmentList must be defined and referenced in the PlantLoop object of the collector loop. An example of a differential thermostat, recirculation for freeze prevention, and high temperature cutoff is shown below:

```

AvailabilityManagerAssignmentList,
  Collector Loop Availability Manager List,           !- Name
  AvailabilityManager:HighTemperatureTurnOff,        !- Availability Manager 1 Object Type
  High Temperature Turn Off Availability Manager,    !- Availability Manager 1 Name
  AvailabilityManager:HighTemperatureTurnOn,         !- Availability Manager 2 Object Type
  Low Temperature Turn On Availability Manager,      !- Availability Manager 2 Name
  AvailabilityManager:DifferentialThermostat,       !- Availability Manager 3 Object Type
  Differential Thermostat Availability Manager;     !- Availability Manager 3 Name

AvailabilityManager:HighTemperatureTurnOff,          ! For water heater safety

  Differential Thermostat Availability Manager,   !- Name
  Collector Outlet Node,                        !- Hot Node Name
  Water Heater Source Outlet Node,             !- Cold Node Name
  10.0,                                         !- Temperature Difference On Limit (delta C)
  2.0;                                         !- Temperature Difference Off Limit (delta C)

```

The AvailabilityManager:DifferentialThermostat object must always be the last manager in the availability manager list. See the AvailabilityManagerAssignmentList object documentation for more information.

SolarCollector:UnglazedTranspired

This object is used to model unglazed transpired solar collectors (UTSC) used to condition outdoor air. These collectors are generally used to heat air drawn through perforated absorbers that are heated by the sun and also recover heat conducted out through the underlying wall. The SolarCollector:UnglazedTranspired object represents a single collector attached to one or more BuildingSurface:Detailed objects and to one or more outdoor air systems. Therefore the transpired collector is part of both the thermal envelope and the HVAC system. An example file is provided called TranspiredCollectors.idf.

The area and orientation of the collector is obtained from BuildingSurface:Detailed objects, which are referenced by name. Although the collector surface itself is slightly detached from the underlying building wall (or roof), no additional surface object is needed to represent the collector itself. When modeling transpired collectors, it is important to consider the size of the collector when developing the building model's BuildingSurface:Detailed objects because the underlying surfaces must match the collector. For example, if the collector covers only part of the wall, then that wall should be split into separate surfaces where one matches the size of the collector. A single collector can be associated with as many BuildingSurface:Detailed objects as desired (although if you need to use more than 10 surfaces, then the IDD will need to be extended). The collector can be arranged at any tilt angle by describing the surfaces appropriately. The surfaces need not be contiguous nor have the same orientation, but the program will issue warnings if surfaces have widely ranging tilts and azimuths.

The collector conditions outdoor air and is connected to the outdoor air system using the usual method of specifying node names. Using the UTSC model requires specifying a relatively complete HVAC air system that includes an outdoor air path. This will typically require using a set of objects that, at a minimum, will include: AirLoopHVAC:ControllerList, AirLoopHVAC:OutdoorAirSystem:EquipmentList, AirLoopHVAC:OutdoorAirSystem, OutdoorAir:NodeList, OutdoorAir:Mixer, SetpointManager:MixedAir, and Controller:OutdoorAir. A single UTSC can serve more than one outdoor air system but requires also using a separate object, called SolarCollector:UnglazedTranspired:MultiSystem to specify node connections.

Controls for the UTSC involve setting the rate of air flow and the status of a bypass damper. If the bypass damper is open, then all the ventilation air goes straight into the outdoor air mixer; if it closed, then all the air first passes through the UTSC. The bypass damper is modeled as completely open or completely closed. The UTSC bypass damper control is determined by an availability manager, the airflow set by the outdoor air mixer controls, and thermostatic type controls that decide if heating is useful. An availability schedule is used to bypass the collector for certain times of the year, eg. summer cooling season. The air flow rates are set by controls associated with the outdoor air mixer (see SetpointManager:MixedAir, and Controller:OutdoorAir). Thermostatic type control decides if the collector will provide useful heating based on either of two types of setpoints. The first type of temperature setpoint is managed by SetpointManager:MixedAir, where the UTSC model looks at a control node, usually the mixed air node. The second type is an extra setpoint especially for free heating that is managed within this object where the UTSC model looks at the zone air node.

Field: Name

This field contains a unique name for the unglazed transpired solar collector.

Field: Boundary Conditions Model Name

This field contains the name of a SurfaceProperty:OtherSideConditionsModel object declared elsewhere in the input file. This will connect the collector to the exterior boundary conditions for the underlying heat transfer surface.

Field: Availability Schedule Name

This field contains the name of a schedule that determines whether or not the UTSC is available. When the schedule value is zero, the UTSC is always bypassed. When the schedule value is greater than zero, the UTSC is available and will be used when other conditions are met, such as outdoor air requested by mixer and preheating has been determined to be beneficial based on thermostatic control.

Field: Inlet Node Name

This field contains the name of an air node that provides air into the UTSC. This node name should also be assigned to be an outdoor air node using the OutdoorAir:NodeList or OutdoorAir:Node objects. This node should also be named as the actuated node in a Controller:OutdoorAir object. If the UTSC is connected to more than one air system, then this field can be left blank and the SolarCollector:UnglazedTranspired:MultiSystem object should be used to define the nodes.

Field: Outlet Node Name

This field contains the name of an air node that is the outlet of the UTSC. This node name will typically be the inlet to the OutdoorAir:Mixer (if there is no other equipment on the outdoor air path). If the UTSC is connected to more than one air system, then this field can be left blank and the SolarCollector:UnglazedTranspired:MultiSystem object should be used to define the nodes.

Field: Setpoint Node Name

This field contains the name of an air node that has a setpoint manager controlling its temperature setpoint. This node name will typically be named as the control node in a Controller:OutdoorAir object. If the UTSC is connected to more than one air system, then this field can be left blank and the SolarCollector:UnglazedTranspired:MultiSystem object should be used to define the nodes.

Field: Zone Node Name

This field contains the name of an air node for a thermal zone that is ultimately connected to the air system. This node is used with the setpoint schedule, defined in the following field, to

provide an added layer of thermostatic control for the UTSC without affecting the control of auxiliary heating. If there is a single air system that is connected to more than one zone, then a single zone should be selected based on where the thermostat might be located. If the UTSC is connected to more than one air system, then this field can be left blank and the SolarCollector:UnglazedTranspired:MultiSystem object should be used to define the nodes.

Field: Free Heating Setpoint Schedule Name

This field contains the name of a temperature schedule defined elsewhere in the input file. This schedule should define temperatures *desired* in the zone, but not necessarily *required*. This secondary setpoint schedule is used to allow the UTSC to operate as if it has its own thermostat that is separate from the primary control mechanism. When the UTSC is used with auxiliary heating, the usual setpoint managers and temperature controllers will determine how the auxiliary heaters are controlled. This allows using a higher zone air temperature setpoint for controlling UTSC bypass than for the auxiliary heating system.

Field: Diameter of Perforations in Collector

This field is used to enter the effective diameter of the perforations in the collector surface. The diameter should be entered in meters. For perforations other than round, use an equivalent diameter for a round hole that would have the same area.

Field: Distance Between Perforations in Collector

This field is used to enter the pitch, or average, shortest distance between perforations.

Field: Thermal Emissivity of Collector Surface

This field is used to enter the thermal emissivity of the collector. This surface property is for longwave infrared radiation. The property is used for both sides of collector. Most painted materials have an emissivity of 0.9.

Field: Solar Absorbtivity of Collector Surface

This field is used to enter the solar absorbtivity of the collector. This surface property is for shortwave, solar radiation. The property is used for the front side of the collector that faces the environment. Darker colors have a higher absorbtivity. While black is the highest performance, other colors might be used to match the color scheme of the rest of the facade. The following table provides sample solar absorbtivities for different colors (source: Conserval Engineering Inc., Toronto, Ontario, Canada).

Color Name of Kynar® ⁸ Paint	Solar Absorptivity
Black	0.94
Classic Bronze	0.91
Chocolate Brown	0.90
Hartford Green	0.90

Bone White	0.30

Field: Effective Overall Height of Collector

This field is used to enter a nominal height for the collector. This value is used in the program to determine a length scale in the vertical direction for the buoyancy-driven portion of natural ventilation that occurs when the collector is inactive. (Note that most of the geometry information is obtained from the underlying surfaces.) The value entered here is adjusted inside the program to account for tilt of the collector. While the value here would generally correspond to the actual distance/height, its value is not critical and it can be used to adjust modeling the air exchange rates in passive mode. If the collector is horizontal, then the length scale is obtained from the following field.

Field: Effective Gap Thickness of Plenum Behind Collector

This field is used to enter a nominal gap thickness for the collector. This distance value is only used when the collector is near horizontal to determine a length scale in the vertical direction for buoyancy calculations. For example, if the collector is mounted on a flat roof, its tilt-adjusted height is zero and the program will use this gap thickness as a length scale rather than the height from the previous field.

Field: Effective Cross Section Area of Plenum Behind Collector

This field is used to enter the nominal cross sectional area of the gap behind the collector. This area is used to determine a velocity scale for surface convection heat transfer correlations when the collector is active. This value is generally the average gap thickness times the average width of the collector.

Field: Hole Layout Pattern for Pitch

This field is used to describe the pattern of perforations in the collector surface. There are currently two choices available: Square and Triangle. Note that the hole layout pattern should be consistent with how the value for pitch was determined.

Field: Heat Exchange Effectiveness Correlation

This field is used to select which correlation is used to model heat transfer from the collector surface to the incoming air when the collector is active. There are two choices available: Kutscher1994, and VanDeckerHollandsBrunger2001. See the Engineering Reference for details and references.

Field: Ratio of Actual Collector Surface Area to Projected Surface Area

This field is used to enter a factor that accounts for the extra surface area resulting from corrugations in the collector surface. Corrugations help stiffen the collector. The projected surface area is obtained by the program from the (flat) underlying surfaces. If the collector is flat then this ratio is 1.0. If the collector is corrugated, then this ratio will be greater than one. A typical value might be 1.165.

Field: Roughness of Collector

This field is used to describe the relative roughness of the collector material. This field is similar to one in the Material object. This parameter only influences the convection coefficients, more specifically the outside convection coefficient. A special keyword is expected in this field with the options being "VeryRough", "Rough", "MediumRough", "MediumSmooth", "Smooth", and "VerySmooth" in order of roughest to smoothest options.

Field: Collector Thickness

This field is used to enter the thickness of the collector material. This value is only needed for the Van Decker Hollands Brunger 2001 correlation. The material thickness should be entered in meters.

Field: Effectiveness for Perforations with Respect to Wind

This field is used to enter a value for the coefficient used to determine natural air exchanges from wind, or Cv. When the collector is inactive, wind will cause exterior air to move in and out of the collector. Cv is an arbitrary coefficient used to model the effectiveness of openings and depends on opening geometry and the orientation with respect to the wind. Cv should probably be in the range 0.25 to 0.65. Increasing Cv will increase the amount of natural ventilation.

Field: Discharge Coefficient for Openings with Respect to Buoyancy Driven Flow

This field is used to enter a value for the coefficient used to determine natural air exchanges from buoyancy, or Cd. When the collector is inactive, stack or buoyancy effects will cause exterior air to move in and out of the collector. Cd is an arbitrary discharge coefficient that depends on the geometry of the opening. Cd should probably be in the range 0.4 to 1.0. Increasing Cd will increase the amount of natural ventilation.

Field: Surface <#> Name

The remaining fields are used to name the BuildingSurface:Detailed objects that are associated with the UTSC. These are the underlying heat transfer surfaces and are defined elsewhere in the input file. These other surfaces should all specify OtherSideConditionsModel as their exterior environment. The input object can currently accommodate up to ten surfaces, but it is extensible.

An example of this object follows.

UTSC Heat Exchanger Effectiveness []

The results from UTSC correlations defined by $\epsilon_{HX} = \frac{T_{a,HX} - T_{amb}}{T_{s,coll} - T_{amb}}$.

UTSC Leaving Air Drybulb from Collector [C]

The temperature of air entering the plenum after being heated by the collector.

UTSC Average Suction Face Velocity [m/s]

The bulk velocity of air approaching the collector.

UTSC Collector Temperature [C]

The surface temperature of the collector itself.

UTSC Plenum Drybulb Temperature [C]

The temperature of air inside, and leaving, the plenum behind the collector.

UTSC Sensible Heating Rate [W]

The overall rate at which heat is being added to the outdoor air stream.

SolarAir:Facility [J]

A meter that includes the heating energy provided by the UTSC.

SolarAir:HVAC [J]

A meter that includes the heating energy provided by the UTSC.

HeatProduced:SolarAir [J]

A meter that includes the heating energy provided by the UTSC.

UTSC Sensible Heating Energy [J]

The overall sum of energy added to the outdoor air stream.

UTSC Air Changes per Hour Passive [ACH]

The rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive in Air Changes per Hour.

UTSC Total Natural Vent Mass Flow [kg/s]

The mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive.

UTSC Total Natural Vent Mass Flow from Wind [kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to wind-driven forces.

UTSC Total Natural Vent Mass Flow from Bouyancy [kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to bouyancy-driven forces.

UTSC Incident Solar Radiation [W/m²]

The intensity of solar radiation incident on the UTSC collector from all sources.

UTSC Overall Efficiency []

The efficiency of the UTSC system including collected solar energy and heat recovered from the underlying surface.

UTSC Collector Efficiency []

The efficiency of the UTSC solar collector.

SolarCollector:UnglazedTranspired:MultiSystem

This object is used to model unglazed transpired solar collectors (UTSC) that are connected to multiple outdoor air systems. This object supplements the SolarCollector:UnglazedTranspired object and is only necessary if more than one air system is connected to a single transpired collector. After the name field, there are sets of four node names used to define the connections of each air system. Each set contains node names for inlet, outlet, control, and zone. If more than five air systems are needed, this object is extensible.

Field: Solar Collector Name

This field is used to identify the name of the SolarCollector:UnglazedTranspired object that needs to be connected to more than one air system. This field must match the name.

Field Set: Inlet Node, Outlet Node, Mixed Air Node, Zone Node

The following four fields form a repeating set of four fields. One set is used for each outdoor air system that is connected to the collector.

Field: Outdoor Air System <#> Collector Inlet Node

This field contains the name of an air node that provides air into the UTSC. This node name should also be assigned to be an outdoor air node using the OutdoorAir:NodeList and OutdoorAir:Node objects. This node is also be named as the actuator node in a Controller:OutdoorAir object.

Field: Outdoor Air System <#> Collector Outlet Node

This field contains the name of an air node that is the outlet of the UTSC. This node name will typically be the Outdoor Air Stream Node Name in the OutdoorAir:Mixer (if there is no other equipment on the outdoor air path).

Field: Outdoor Air System <#> Mixed Air Node

This field contains the name of an air node that has a setpoint manager controlling its temperature setpoint. This node name will typically be named as the mixed air node in a Controller:OutdoorAir object.

Field: Outdoor Air System <#> Zone Node

This field contains the name of an air node for a thermal zone that is ultimately connected to the air system. This node is used with the setpoint schedule, defined in the following field, to provide an added layer of thermostatic control for the UTSC without affecting the control of auxiliary heating. If there is a single air system that is connected to more than one zone, then a single zone should be selected based on where the thermostat might be located.

An example of this object follows.

```
SolarCollector:UnglazedTranspired:Multisystem,
OFFICE MultiSystem OA UTSC , ! Solar Collector Name
Outside Air Inlet Node ZN1, ! Outdoor Air System 1 Collector Inlet Node
UTSC Outlet Node ZN1, ! Outdoor Air System 1 Collector Outlet Node

```

Group – Pumps

EnergyPlus plant and condenser loops need pump components to drive liquid flow around the loop. There are various types of pump models available.

Pump:VariableSpeed

Pumps are needed in both plant and condenser loops. The syntax for a variable speed pump is given below.

Field: Name

This alpha field contains the identifying a unique name for the pump.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump outlet node.

Field: Rated Flow Rate

This numeric field contains the pump's rated volumetric flow rate in cubic meters per second.

Field: Rated Pump Head

This numeric field contains the pump's rated head pressure in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump's rated power consumption in Watts. If the user is performing a pressure simulation on the loop in which this pump is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Coefficient 1 of the Part Load Performance Curve

This numeric field contains the first coefficient in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$\text{FractionFullLoadPower} = C_1 + C_2 \text{PLR} + C_3 \text{PLR}^2 + C_4 \text{PLR}^3$$

where C_1, C_2, C_3 , and C_4 are Coefficients 1 – 4 (below) and PLR is the Part Load Ratio.

Field: Coefficient 2 of the Part Load Performance Curve

This numeric field contains the second coefficient in the part load ratio curve.

Field: Coefficient 3 of the Part Load Performance Curve

This numeric field contains the third coefficient in the part load ratio curve.

Field: Coefficient 4 of the Part Load Performance Curve

This numeric field contains the fourth coefficient in the part load ratio curve.

Field: Minimum Flow Rate

This field contains the minimum volumetric flow rate while operating in variable flow capacity rate in cubic meters per second.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. A variable speed pump is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump is operating intermittently, then the pump can shutdown. For any other condition such as the loop having a load and the pump is operating intermittently or the pump is continuously operating (regardless of the loading condition), the pump will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump is running, it will try to meet the flow request made by demand side components. Applicable availability managers (ref. AvailabilityManagerAssignmentList) may override this control by forcing the pump to be on or off.

Field: Pump Flow Rate Schedule Name

The schedule values modify the value for Rated Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

Field: Pump Curve Name

This references a pump curve to be used during pump flow-loop head resolution. This is only applicable for loop simulations which include pressure components on at least a single branch. More information regarding pressure system simulation is available in the engineering reference.

Field: Impeller Diameter

For pressure simulation cases, this is the impeller diameter used during calculations which is used in non-dimensionalizing the pump curve described in the previous field. The units of this value are meters.

Field: VFD Control Type

This string defines which type of VFD control type to perform. PressureSetPointControl is a realistic approach which requires inputs of pressure range schedules to control the pump rpm to maintain a certain pressure drop (head). ManualControl is an idealized control strategy in which the pump RPM is maintained at a scheduled value throughout the simulation, abiding by other flow restrictions in the loop.

Field: Pump RPM Schedule Name

For VFD Control Type = ManualControl, this defines the pump RPM schedule to use during the simulation. For VFD Control Type = PressureSetPointControl, this field is not interpreted. The value of the schedule is RPM.

Field: Minimum Pressure Schedule

For VFD Control Type = PressureSetPointControl, this field defines the minimum pressure range setpoint value, or the lower bound of pressure drop (head) to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is Pascals.

Field: Maximum Pressure Schedule

For VFD Control Type = PressureSetPointControl, this field defines the maximum pressure range setpoint value, or the upper bound of pressure drop (head) to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is Pascals.

Field: Minimum RPM Schedule

For VFD Control Type = PressureSetPointControl, this field defines the minimum allowable RPM, or the lower bound of pump speed to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is RPM.

Field: Maximum RPM Schedule

For VFD Control Type = PressureSetPointControl, this field defines the maximum allowable RPM, or the upper bound of pump speed to use when determining the required pump speed. For VFD Control Type = ManualControl, this field is not interpreted. The value of the schedule is RPM.

Field: Zone Name

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

Field: Skin Loss Radiative Fraction

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

Pump:VariableSpeed Outputs

HVAC,Average,Pump Electric Power [W]

HVAC, Sum, Pump Electric Consumption [J]
HVAC, Average, Pump Shaft Power [W]
HVAC, Average, Pump Heat To Fluid [W]
HVAC, Sum, Pump Heat To Fluid Energy [J]
HVAC, Average, Pump Outlet Temp [C]
HVAC, Average, Pump Mass Flow Rate [kg/s]
HVAC, Average, Pump Heat Loss to Zone Rate [W]
HVAC, Sum, Pump Heat Loss to Zone [J]
HVAC, Average, Pump Convection Heat Loss to Zone Rate [W]
HVAC, Average, Pump Radiation Heat Loss to Zone Rate [W]

Pump Electric Power [W]**Pump Electric Consumption [J]**

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

Pump Heat To Fluid [W]**Pump Heat To Fluid Energy [J]**

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

Pump Outlet Temp [C]**Pump Mass Flow Rate [kg/s]**

These outputs are the water outlet temperature and mass flow rate.

Pump Heat Loss to Zone Rate [W]**Pump Heat Loss to Zone [J]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

Pump Convection Heat Loss to Zone Rate [W]

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

Pump Radiation Heat Loss to Zone Rate [W]

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

Pump:ConstantSpeed

Pumps may be found in both plant and condenser loops. The syntax for a constant speed pump is given below.

Field: Name

This alpha field contains the identifying name for the pump.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump outlet node.

Field: Rated Flow Rate

This numeric field contains the pump's rated volumetric flow rate in cubic meters per second.

Field: Rated Pump Head

This numeric field contains the pump's rated head pressure in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump's rated power consumption in Watts. If the user is performing a pressure simulation on the loop in which this pump is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. The operation of a constant speed pump is fairly straightforward. If the user designates a constant speed pump that is operating continuously, the pump will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump is constant speed and operates intermittently, the pump will run at its capacity if a load is sensed and will shut off if there is no load on the loop. Applicable availability managers (ref. AvailabilityManagerAssignmentList) may override this control by forcing the pump to be on or off.

Field: Pump Flow Rate Schedule Name

The schedule values modify the Rated Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

Field: Pump Curve Name

This field is only used if the user is performing a pressure-based simulation in the plantloop of the "LoopFlowCorrection" type (see PlantLoop section for how to enable this).

This field references a separate pressure head curve that the user has input separately in the input file. The pressure curve represents a non-dimensional regression of pressure-flow rate data. The equation should be of the following form:

$$\psi = C_4 \times \varphi^4 + C_3 \times \varphi^3 + C_2 \times \varphi^2 + C_1 \times \varphi + C_0.$$

In this equation, the two dimensionless parameters, X and X are defined in terms of physical pump and flow parameters as:

$$\psi = \frac{\Delta P}{\rho N^2 D^2}$$

$$\varphi = \frac{\dot{m}}{\rho ND^3}$$

Where “Delta P” is the pressure drop, mdot is the fluid mass flow rate, rho is a representative fluid density, N is the rotational speed of the pump, and D is the pump impeller diameter.

Since the user may not need a full fourth order expansion of this, the user may use linear (first order), quadratic (second order), cubic (third order), or full quartic (fourth order). These are available in the objects Curve:Linear, Curve:Quadratic, Curve:Cubic, Curve:Quartic.

Once this curve is input properly (along with the following two fields), the pump will respond to the plant loop pressure drop when resolving the flow rate. Note that this simulation method will likely result in a plant loop that does not exactly hit the setpoint as the current simulation method does. This is due to the loop flow rate now being “pressure-based” and not “decision-based”.

Field: Impeller Diameter

This field is only used if the user is performing a pressure-based simulation in the plantloop of the “LoopFlowCorrection” type (see PlantLoop section for how to enable this).

To “re-dimensionalize” the dimensionless pump curve, the impeller diameter must be known. This value is entered in meters.

Field: Rotational Speed

This field is only used if the user is performing a pressure-based simulation in the plantloop of the “LoopFlowCorrection” type (see PlantLoop section for how to enable this).

To “re-dimensionalize” the dimensionless pump curve, the rotational speed must be known. This value is entered in RPM (revolutions per minute).

Field: Zone Name

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

Field: Skin Loss Radiative Fraction

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

An example of this object follows.

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

Pump Outlet Temp [C]**Pump Mass Flow Rate [kg/s]**

These outputs are the water outlet temperature and mass flow rate.

Pump:VariableSpeed:Condensate

The Pump:VariableSpeed:Condensate object can only be used in steam system simulation for the condensate side of the loop. This is a variable speed pump, which pumps the condensate back to the steam boiler. The syntax for condensate pump is given below.

Field: Name

This alpha field contains the identifying unique name for the pump.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump outlet node.

Field: Rated Flow Rate

This numeric field contains the pump's rated volumetric flow rate in cubic meters per second.

Field: Rated Pump Head

This numeric field contains the pump's rated head in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump's rated power consumption in Watts. If the user is performing a pressure simulation on the loop in which this pump is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Coefficient 1 of the Part Load Performance Curve

This numeric field contains the first coefficient in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$\text{FractionFullLoadPower} = C_1 + C_2 \text{PLR} + C_3 \text{PLR}^2 + C_4 \text{PLR}^3$$

where C_1, C_2, C_3 , and C_4 are Coefficients 1 – 4 (below) and PLR is the Part Load Ratio.

Field: Coefficient 2 of the Part Load Performance Curve

This numeric field contains the second coefficient in the part load ratio curve.

Field: Coefficient 3 of the Part Load Performance Curve

This numeric field contains the third coefficient in the part load ratio curve.

Field: Coefficient 4 of the Part Load Performance Curve

This numeric field contains the fourth coefficient in the part load ratio curve.

Field: Pump Flow Rate Schedule Name

The schedule values modify the Rated Flow Rate of the pump on a time basis the default is that the pump is ON and runs according to its other operational requirements specified above. The schedule is for special, not typical pump operations.

Field: Zone Name

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

Field: Skin Loss Radiative Fraction

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

HeaderedPumps:ConstantSpeed

Headered pumps are components with more than one identical pumps connected in parallel. The syntax for HeaderedPumps:ConstantSpeed is as follows.

Field: Name

This alpha field contains the identifying name for the pump bank.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump bank inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump bank outlet node.

Field: Total Rated Flow Rate

This numeric field contains the pump bank's rated volumetric flow rate in cubic meters per second. This is equal to the product of number of pumps and the flow rate of each individual pump. The field can be autosized.

Field: Number of Pumps in Bank

The numeric field specifies the number of pumps present in the pump bank. All these pumps are connected in parallel internally.

Field: Flow Sequencing Control Scheme

The alpha field specifies the scheme for sequencing flow. Currently the only choice is Sequential, where a pump in the pump bank will be turned ON only after fully loading the previous pump.

Field: Rated Pump Head

This numeric field contains the pump's rated head pressure in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump bank's total power consumption in Watts. This field is equal to the product of number of pumps and the rated power consumption of each individual pump. If the user is performing a pressure simulation on the loop in which this pump bank is found, this value would only be used to estimate pump efficiency. During reported

calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically.

Field: Motor Efficiency

This numeric field contains the pump's efficiency in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the pump's fraction of power loss to the fluid.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. The operation of a constant speed pump bank is fairly straightforward. If the user designates a constant speed pump bank that is operating continuously, the pump bank will run regardless of whether or not there is a load. This may have the net effect of adding heat to the loop if no equipment is turned on. If the pump bank is constant speed and operates intermittently, the pump bank will run at its capacity if a load is sensed and will shut off if there is no load on the loop. Applicable availability managers (ref. AvailabilityManagerAssignmentList) may override this control by forcing the pump to be on or off.

Field: Pump Flow Rate Schedule Name

The schedule values modify the Total Rated Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

Field: Zone Name

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

Field: Skin Loss Radiative Fraction

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

An example for constant speed pump bank follows.

HVAC,Average,Number of Pumps Operating []
HVAC, Average, Pump Heat Loss to Zone Rate [W]
HVAC, Sum, Pump Heat Loss to Zone [J]
HVAC, Average, Pump Convection Heat Loss to Zone Rate [W]
HVAC, Average, Pump Radiation Heat Loss to Zone Rate [W]

Pump Electric Power [W]**Pump Electric Consumption [J]**

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

Pump Heat To Fluid [W]**Pump Heat To Fluid Energy [J]**

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

Pump Outlet Temp [C]**Pump Mass Flow Rate [kg/s]**

These outputs are the water outlet temperature and mass flow rate.

Number of Pumps Operating []

This output tells the number of pumps in the pump bank operating at any reporting frequency.

Pump Heat Loss to Zone Rate [W]**Pump Heat Loss to Zone [J]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

Pump Convection Heat Loss to Zone Rate [W]

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

Pump Radiation Heat Loss to Zone Rate [W]

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

HeaderedPumps:VariableSpeed

Headered pumps are components with more than one identical pumps connected in parallel. Currently this object may be found only in plant loops. The syntax for a HeaderedPumps:VariableSpeed pump is given below.

Field: Name

This alpha field contains the identifying unique name for the pump bank.

Field: Inlet Node Name

This alpha field contains the identifying name for the pump bank inlet node.

Field: Outlet Node Name

This alpha field contains the identifying name for the pump bank outlet node.

Field: Total Rated Flow Rate

This numeric field contains the pump bank's rated volumetric flow rate in cubic meters per second. This is equal to the product of number of pumps and the flow rate of each individual pump. The field can be autosized.

Field: Number of Pumps in Bank

The numeric field specifies the number of pumps present in the pump bank. All these pumps are connected in parallel internally.

Field: Flow Sequencing Control Scheme

The alpha field specifies the scheme for sequencing flow. Currently the only choice is Sequential, where a pump in the pump bank will be turned ON only after fully loading the previous pump.

Field: Rated Pump Head

This numeric field contains the pump's rated head in Pascals.

Field: Rated Power Consumption

This numeric field contains the pump bank's total power consumption in Watts. This field is equal to the product of number of pumps and the rated power consumption of each individual pump. If the user is performing a pressure simulation on the loop in which this pump bank is found, this value would only be used to estimate pump efficiency. During reported calculations, the pump would use the loop pressure drop and current flow conditions along with efficiency to calculate pump power dynamically.

Field: Motor Efficiency

This numeric field contains the efficiency of the individual pump (which will be equivalent to pump bank efficiency) in decimal form (0 = 0%, 1 = 100%).

Field: Fraction of Motor Inefficiencies to Fluid Stream

This numeric field contains the individual pump's fraction of power loss to the fluid.

Field: Coefficient 1 of the Part Load Performance Curve

This numeric field contains the first coefficient (C_1) in the part load ratio curve. The fraction of full load power is determined by the cubic equation:

$$\text{FractionFullLoadPower} = C_1 + C_2 \text{PLR} + C_3 \text{PLR}^2 + C_4 \text{PLR}^3$$

where C_1, C_2, C_3 , and C_4 are Coefficients 1 – 4 (below) and PLR is the Part Load Ratio.

Field: Coefficient 2 of the Part Load Performance Curve

This numeric field contains the second coefficient (C_2) in the part load ratio curve.

Field: Coefficient 3 of the Part Load Performance Curve

This numeric field contains the third coefficient (C_3) in the part load ratio curve.

Field: Coefficient 4 of the Part Load Performance Curve

This numeric field contains the fourth coefficient (C_4) in the part load ratio curve.

Field: Minimum Flow Rate

The numeric field specifies the minimum flow allowed for the pump bank as a fraction of the nominal flow. If the requested flow is less than minimum flow pump bank runs at minimum flow.

Field: Pump Control Type

This is a choice field of Continuous or Intermittent. A variable speed pump bank is defined with maximum and minimum flow rates that are the physical limits of the device. If there is no load on the loop and the pump bank is operating intermittently, then the bank can shutdown. For any other condition such as the loop having a load and the pump bank is operating intermittently or the pump bank is continuously operating (regardless of the loading condition), the bank will operate and select a flow somewhere between the minimum and maximum limits. In these cases where the pump bank is running, it will try to meet the flow request made by demand side components. Applicable availability managers (ref. AvailabilityManagerAssignmentList) may override this control by forcing the pump to be on or off.

Field: Pump Flow Rate Schedule Name

Modifies the Rated Volumetric Flow Rate of the pump on a time basis. The default is that the pump is ON and runs according to its other operational requirements specified above. This schedule is for special, not typical pump operations.

Field: Zone Name

This field is optional. It can be used to input the name of the Zone in which the pump is located in the model. If the pump is outdoors, or skin losses are not to be modeled, then leave this field blank. If a valid Zone name is entered, then the portion of electrical power consumed by the pump that is not added to the working fluid is added to the surrounding Zone.

Field: Skin Loss Radiative Fraction

This field is optional. If a Zone is named in the previous field and pump losses are to be added to a surrounding thermal zone, then this input determines the split between thermal radiation and thermal convection for the heat losses from the pump. If it is left blank then all the losses will be convective.

An example of this object follows.

Pump Electric Power [W]

Pump Electric Consumption [J]

These outputs are the electric power input to the pump motor. Consumption is metered on Pumps:Electricity, Electricity:Plant, and Electricity:Facility.

Pump Shaft Power [W]

This is the shaft power delivered from the motor to the pump.

Pump Heat To Fluid [W]

Pump Heat To Fluid Energy [J]

These outputs are the energy added to the fluid as heat. For the current algorithm, this is equal to Pump Shaft Power, because the loops are closed and all energy added to the fluid will ultimately become heat due to friction.

Pump Outlet Temp [C]

Pump Mass Flow Rate [kg/s]

These outputs are the water outlet temperature and mass flow rate.

Number of Pumps Operating []

This output tells the number of pumps in the pump bank operating at any reporting frequency.

Pump Heat Loss to Zone Rate [W]**Pump Heat Loss to Zone [J]**

These outputs are the thermal losses from the pump to the surrounding Zone. They are only available if a Zone was named in the pump's input. These indicate the amount of heat added to the zone from the pump's inefficiencies. They are the total heat loss including both convection and radiation.

Pump Convection Heat Loss to Zone Rate [W]

This output is the thermal loss from the pump to the surrounding Zone in the form of convective gains directly to the zone air. It is only available if a Zone was named in the pump input.

Pump Radiation Heat Loss to Zone Rate [W]

This output is the thermal loss from the pump to the surrounding Zone in the form of thermal radiation gains directly to the inside face of the zone's surfaces. It is only available if a Zone was named in the pump input.

Group – Heating and Cooling Coils

Several different coils may be added to zone equipment and air loops. This includes simple heating (gas, electric, and hot water) and a simple water-cooling coil as well as a more detailed flat fin water-cooling coil model. In general, the heating coil description can be used for a heating coil, a reheat coil, or a preheat coil in the air loop simulation or for zone equipment. Figure 122 is an example of a heating and cooling coil in the air loop simulation in a dual duct system. This does show the basic node structure that will be referenced in the input description. The figure does show water coils since they are the most complex to input in the simulation compared to the Electric and Gas coils which only have air connections.

Figure 122. Example Air Loop Heating & Cooling Coil

Coil:Cooling:Water

The water cooling coil (Coil:Cooling:Water) has the ability to give detailed output with simplified inputs, inputting complicated coil geometry is not required by the user for this model instead the coil is sized in terms of auto-sizeable thermodynamic inputs. The coil requires thermodynamic inputs such as temperatures, mass flow rates and humidity ratios.

The coil is sized using auto-sized/user design input conditions and the UA values are calculated from the design conditions. A rough estimate of the coil area is provided along with percentage of surface wet and/or dry. This model uses the NTU-effectiveness approach to model heat transfer and has two types of flow arrangements cross-flow or counter-flow.

The basic underlying idea is - use auto sizable thermodynamic design inputs, calculate the coil UA's, use these UA values and operating conditions from the nodes connections, calculate the outlet stream conditions, and calculate the heat transfer rates.

See section “Cooling Coil Model” in the EnergyPlus Engineering Document for further details regarding this model.

Field: Name

A unique user-assigned name for an instance of a cooling coil. Any reference to this cooling coil by another object will use this name.

Field: Available Schedule Name

Schedule that defines when the coil is available. The name of the schedule (ref: Schedule) that denotes whether the cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit is off.

Field: Design Water Flow Rate

The maximum possible water volume flow rate (m^3/sec) through the coil. This is an auto sizable design input.

Field: Design Air Flow Rate

The maximum possible air volume flow rate (m^3/sec) through the coil. This is an auto sizable design input.

Field: Design Inlet Water Temperature

The inlet water temperature for the design flow (deg C). This is an auto sizable design input.

Field: Design Inlet Air Temperature

The inlet air temperature for the design flow (deg C). This is an auto sizable design input.

Field: Design Outlet Air Temperature

The outlet air condition desired for design flow (deg C). This is an auto sizable design input.

Field: Design Inlet Air Humidity Ratio

The highest value of humidity ratio possible for the Design inlet air stream. This is an auto sizable input.

Field: Design Outlet Air Humidity Ratio

The value of humidity ratio for the Design outlet air stream, it is an auto sizable input.

Field: Water Inlet Node Name

The name of the water coil inlet from the chilled water loop, i.e. Cooling Coil Water Inlet Node. It is from this node the operating inputs for water are transferred to the coil.

Field: Water Outlet Node Name

The name of the water coil outlet from the chilled water loop, i.e. Cooling Coil Water Outlet Node. It is from this node the operating output for water are reported to the coil.

Field: Air Inlet Node Name

The name of the air inlet to the water coil, i.e. Cooling Coil Air Inlet Node. It is from this node the operating inputs for air are transferred to the coil.

Field: Air Outlet Node Name

The name of the air outlet from the water coil, i.e. Cooling Coil Air Outlet Node. It is from this node the operating output for airside is reported to the coil.

Field: Type of Analysis

The coil has two modes of operation, termed as **SimpleAnalysis** and **DetailedAnalysis**. The difference between the two modes being, the simple mode reports the value of surface area fraction wet of the coil as dry or wet. The detailed mode give the exact value, however the execution time in detailed mode is noticeably higher.

Field: Heat Exchanger Configuration

The coil is operable in two modes, Cross Flow for general A/C applications and Counter flow mode. Air-conditioning systems generally use cross flow heat exchangers, hence the default is set to cross flow.

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Examples when auto sized in an IDF are as below:

```
Coil:Cooling:Water,
  Main Cooling Coil 1,      !- Coil Name
  CoolingCoilAvailSched,   !- Available Schedule
  autosize,               !- Design Water Volume Flow Rate of Coil {m3/s}
  autosize,               !- Design Air Flow Rate of Coil {m3/s}

  Mixed Air Node 1,          !- Coil_Air_Inlet_Node
  Main Cooling Coil 1 Outlet Node;       !- Coil_Air_Outlet_Node
```

Coil:Cooling:Water Outputs

Following are the list of possible output variables from this coil model:

```
HVAC,Sum,Total Water Cooling Coil Energy[J]
HVAC,Sum,Sensible Water Cooling Coil Energy[J]
HVAC,Average,Total Water Cooling Coil Rate[W]
HVAC,Average,Sensible Water Cooling Coil Rate[W]
HVAC,Average,Cooling Coil Area Wet Fraction
HVAC,Average,Cooling Coil Condensate Volumetric Flow Rate [m3/s]
Zone,Meter,OnSiteWater:Facility [m3]
Zone,Meter,OnSiteWater:HVAC [m3]
Zone,Meter,Condensate:OnSiteWater [m3]
HVAC,Sum,Cooling Coil Condensate Volume [m3]
```

Total Water Cooling Coil Energy (J)

Total Water Cooling Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Sensible Water Cooling Coil Energy (J)

Sensible Water Cooling Coil Energy is the total amount of Sensible heat transfer taking place in the coil at the operating conditions. It only takes into account temperature difference in the inlet and outlet air streams at operating conditions.

Total Water Cooling Coil Rate (W)

Total Water Cooling Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

Sensible Water Cooling Coil Rate (W)

Sensible Water Cooling Coil Rate is the Rate of Sensible heat transfer taking place in the coil at the operating conditions.

Cooling Coil Area Wet Fraction

It defines the fraction of total surface area of coil which is wet due to moisture condensation on the surface of the coil. Value varies between 0.0 and 1.0.

In addition, if a Water Storage Tank is used to collect coil condensate, then the following outputs will be available.

Cooling Coil Condensate Volumetric Flow Rate [m3/s]

Cooling Coil Condensate Volume [m3]

These reports provide the rate and amount of condensate from the coil. Condensate is water condensed out of the air as a result of cooling. The condensate volume is also reported on the meter for "OnSiteWater."

Coil:Heating:Water

This simple heating coil model only does sensible heating of the air. The simple heating coil uses the Effectiveness-NTU algorithm and assumes a cross-flow heat exchanger.

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: U-Factor Times Area Value

The UA value for the coil needed for the Effectiveness-NTU heat exchanger model. An estimate of the UA can be obtained from:

$$q = UA \times (T_{water,avg} - T_{air,avg})$$

where q is the heat transferred from water to the air in watts; $T_{\text{water, avg}}$ is the average water temperature in degrees C; and $T_{\text{air, avg}}$ is the average air temperature in degrees C. Or the LMTD temperature difference can be used. This field is used when *Performance Input Method* = *UFactorTimesAreaAndDesignWaterFlowRate*. This field is autosizable.

Field: Maximum Water Flow Rate

The maximum possible water flow rate (m^3/sec) through the coil. This field is used when *Coil Performance Input Method* = *UFactorTimesAreaAndDesignWaterFlowRate*. This field is autosizable.

Field: Water Inlet Node Name

The name of the coil's water inlet node from the hot water loop.

Field: Water Outlet Node Name

The name of the coil's water outlet node from the hot water loop.

Field: Air Inlet Node Name

The name of the air inlet node to the water coil.

Field: Air Outlet Node Name

The name of the air outlet node from the water coil.

Field: Performance Input Method

The user can choose either *UFactorTimesAreaAndDesignWaterFlowRate* or *NominalCapacity*. If *UFactorTimesAreaAndDesignWaterFlowRate* is selected, the user must input values for UA of the Coil and Max Water FlowRate of the Coil (and Rated Capacity is ignored). If *NominalCapacity* is chosen, the user must input a Rated Capacity for the coil; UA of the Coil and Max Water FlowRate of the Coil will be ignored. Rated capacity is defined as the heating capacity in watts of the coil at the rating points (i.e., the rated inlet and outlet water/air temperatures defined in the input fields below). The rated capacity is used to calculate a water mass flow rate and a UA for the coil. The default is *NominalCapacity*.

To autosize the capacity, choose *UfactorTimesAreaAndDesignWaterFlowRate* and put autosize as the inputs for *U-Factor Times Area Value*, *Maximum Water Flow Rate*, and *Rated Capacity*. The program will use the Sizing inputs to size the coil. The rated temperatures (see below) are ignored in autosizing. These are used only when the user is specifying coil performance using the *NominalCapacity* input method.

Field: Rated Capacity

The heating capacity of the coil in watts at the rated inlet and outlet air and water temperatures. This field is used when the *Performance Input Method* = *Nominal Capacity*. This field is autosizable. The rating points are given in the four subsequent input fields.

Field: Rated Inlet Water Temperature

The inlet water temperature (degrees C) corresponding to the rated heating capacity. The default is 82.2 degrees C (180 degrees F).

Field: Rated Inlet Air Temperature

The inlet air temperature (degrees C) corresponding to the rated heating capacity. The default is 16.6 degrees C (60 degrees F).

Field: Rated Outlet Water Temperature

The outlet water temperature (degrees C) corresponding to the rated heating capacity. The default is 71.1 degrees C (160 degrees F).

Field: Rated Outlet Air Temperature

The outlet air temperature (degrees C) corresponding to the nominal heating capacity. The default is 32.2 degrees C (90 degrees F).

Field: Rated Ratio for Air and Water Convection

This is the ratio of convective heat transfers between air side and water side of the heating coil at the rated operating conditions. The default is .5. This ratio describes the geometry and the design of the coil and is defined by:

$$ratio = \frac{\eta_f (hA)_{air}}{(hA)_{water}}$$

where,

η_f is the fin efficiency, (dimensionless)

h is the surface convection heat transfer coefficient

A is the surface area

An example input of the object is:

```
Coil:Heating:Water,
  SPACE3-1 Zone Coil,      !- Coil Name
  ReheatCoilAvailSched,    !- Available Schedule

  0.55;                   !- Rated Ratio for Air and Water Convection
```

Coil:Heating:Water Outputs

HVAC,Sum, Total Water Heating Coil Energy[J]
HVAC,Average,Total Water Heating Coil Rate[W]
HVAC,Average,Water Heating Coil U-factor Times Area [W]

Total Water Heating Coil Energy (J)

Total Water Heating Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Total Water Heating Coil Rate (W)

Total Water Heating Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

Water Heating Coil U-factor Times Area (W/K)

This characterizes the overall heat transfer “UA” value, or U-factor times Area. The simple heating coil model adjusts UA value based on inlet temperatures and flow rates and this output contains the results from that adjustment.

Coil:Heating:Steam

The simple steam to air heating coil model only does sensible heating of the air. The steam to air coils condenses the steam and sub cools steam at loop pressure and discharges the condensate through steam traps at low pressure condensate line.

Field: Name

A unique identifying name for each steam coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Maximum Steam Flow Rate

The maximum possible steam flow rate (m^3/sec) through the coil. This field is autosizable.

Field: Degree of SubCooling

Ideally the steam trap located at the outlet of steam coil should remove all the condensate immediately, however there is a delay in this process in actual systems which causes the condensate to SubCool by certain degree in the coil before leaving the coil, this SubCool occurs in the steam coil and this SubCool-heat is added to the zone. The minimum value is $2^\circ C$ Celsius and default is $5^\circ C$ Celsius.

Field: Degree of Loop SubCooling

This essentially represents the heat loss to the atmosphere due to uninsulated condensate return piping to the boiler. Condensate return piping operates at atmospheric pressure and is not insulated. The condensate sub cools to certain degree before it is pumped back to the boiler. The minimum value is $10^\circ C$ Celsius and default is $20^\circ C$ Celsius.

Field: Water Inlet Node Name

The name of the steam coil inlet from the steam loop, i.e. Steam Coil steam inlet node.

Field: Water Outlet Node Name

The name of the steam coil outlet to the condensate loop, i.e. Steam Coil condensate outlet node.

Field: Air Inlet Node Name

The name of the air inlet to the steam coil, i.e. Steam Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the steam coil, i.e. Steam Coil Air Outlet Node.

Field: Coil Control Type

Choice of either **ZoneLoadControl** steam coil or **TemperatureSetpointControl** steam coil. A zone coil is load controlled and an air loop steam coil is temperature controlled.

Field: Temperature Setpoint Node Name

If the coil is used in the air loop simulation and is temperature controlled using a Set Point Manager (i.e., the previous file is TemperatureSetpointConrtol), then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit, the coil is load controlled and a control node set point is not required (i.e., the previous field is ZoneLoadControl).

An example of a Steam Coil input statement (one each for Temperature Controlled and Load Controlled) from an IDF is given below:

```
Coil:Heating:Steam,
  VAV SYS 1 Heating Coil,          !- Coil Name

Coil:Heating:Steam Outputs:

```

HVAC,Sum, Total Steam Coil Heating Energy[J]
HVAC,Average,Total Steam Coil Heating Rate[W]
HVAC,Average,Loop Losses[W]
HVAC, Average, Steam Coil Inlet Temp[C]
HVAC, Average, Steam Coil Outlet Temp [C]
HVAC, Average, Steam Coil Mass Flow Rate [kg/s]

```

Total Steam Heating Coil Energy (J)

Total Steam Heating Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Total Steam Heating Coil Rate (W)

Total Steam Heating Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

HVAC,Average,Loop Losses[W]

Loop losses represent the unavoidable loss due to degree of sub cooling in the condensate return piping back to the boiler and the loss occurring due to flashing of steam across the steam trap due to pressure differential between the steam and the condensate side.

Steam Coil Inlet Temp [C]

Steam Coil Outlet Temp [C]

Steam Coil Mass Flow Rate [kg/s]

These outputs are the Steam inlet and condensate outlet temperatures and steam flow rate for the boiler.

Coil:Heating:Electric

The electric heating coil is a simple capacity model with a user-inputted efficiency. In many cases, this efficiency for the electric coil will be 100%. This coil will be simpler than shown in Figure 122 since it will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled. If used in the air loop simulation it will be controlled to a specified temperature scheduled from the SetPoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand.

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Efficiency

This is user-inputted efficiency (decimal units, not percent) and can account for any loss. In most cases for the electric coil, this will be 100%.

Field: Nominal Capacity

This is the maximum capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

Field: Air Inlet Node Name

The name of the air inlet to the electric coil, i.e. Heating Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the electric coil, i.e. Heating Coil Air Outlet Node.

Field: Temperature Setpoint Node Name

If the coil is used in the air loop simulation and is temperature controlled using a Set Point Manager, then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit, the coil is load controlled and a control node set point is not required.

An example in IDF form:

An example of IDF usage:

```

AHU Reheater Outlet;   !- Temperature Setpoint Node Name
```

Coil:Heating:Electric Outputs

HVAC, Sum, Heating Coil Energy [J]
HVAC, Average, Heating Coil Rate [W]
HVAC, Sum, Heating Coil Electric Consumption [J]
HVAC, Average, Heating Coil Electric Power [W]

Heating Coil Energy (J)

Heating Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Heating Coil Rate[W]

Heating Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

Heating Coil Electric Consumption [J]

Heating Coil electric consumption after the efficiency of the coil has been taken into account in Joules for the timestep reported.

Heating Coil Electric Power [W]

This field is the average Heating Coil electric power after the efficiency of the coil has been taken into account in Watts for the timestep reported.

Coil:Heating:Desuperheater

A simplified approach is used to determine the performance of this air heating coil. The model assumes that the heating energy provided by this coil is reclaimed from the superheated refrigerant gas leaving a compressor (i.e., a desuperheating refrigerant-to-air heating coil) and does not impact the performance of the compressor. This coil can be used in air loop simulations but can't be used by certain compound objects (e.g., AirLoopHVAC:UnitaryHeatPump:AirToAir, AirLoopHVAC:UnitaryHeatPump:WaterToAir, or Dehumidifier:Desiccant:NoFans) or any air distribution equipment (e.g., AirTerminal:SingleDuct:ConstantVolume:Reheat, AirTerminal:SingleDuct:VAV:Reheat, or AirTerminal:SingleDuct:SeriesPIU:Reheat).

The desuperheater heating coil input requires a coil name, an availability schedule, and a heat reclaim recovery efficiency. The reclaim recovery efficiency determines the amount of heat available for use by this heating coil. Approximately 25-30% of the energy rejected by typical refrigeration system condensers is to reduce the superheated refrigerant vapor temperature to the condensing temperature. Recovery efficiencies higher than 30% may cause the refrigerant gas to condense which in turn impacts the performance of the refrigeration system. For this reason, the maximum heat reclaim recovery efficiency for this coil is 30% for most sources of waste heat, including refrigeration compressor racks. The one exception to this 30% limit is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 90% of the heat within the superheated region.

The next two input items for the desuperheater heating coil are the node names for the inlet and outlet air streams. The following two input fields define the source of heating energy for the coil. This desuperheater heating coil may only be used with direct expansion (DX) cooling or refrigeration equipment. The first of these two inputs is the heating source object type while the second defines the name of the heating source. For proper modeling, the desuperheater heating coil must be placed downstream of a DX cooling coil when reclaiming heat from that cooling coil. Desuperheating heating coil placement is unrestricted when reclaiming heat from a Refrigeration:CompressorRack or Refrigeration:Condenser.

The next input field is optional and defines the set point node name if the desuperheater heating coil is to be controlled based on temperature. When a load-based control scheme is used, this field is left blank. A final optional input is used to model parasitic electric energy use of auxiliary equipment associated with the desuperheater heating coil (e.g., solenoid valve).

Field: Name

This alpha field defines a unique user-assigned name for an instance of a desuperheater heating coil. Any reference to this desuperheater heating coil by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the desuperheater heating coil can run during a given time period. Schedule values must range from 0 to 1. A schedule value greater than 0 indicates that the coil can operate during the time period. A value equal to 0 denotes that the coil must be off for that time period.

Field: Heat Reclaim Recovery Efficiency

This numeric field defines the ratio of recovered waste heat from the superheated refrigerant gas to the total rejected waste heat from the heating source (as if no heat reclaim occurred). Values can range from 0.0 up to a maximum of 0.9 if the source is a refrigeration condenser and 0.3 for all other waste heat sources. If this input field is left blank, the default value is 0.8 for a refrigeration condenser source type and 0.25 for all other sources.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the desuperheater heating coil draws its inlet air.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the desuperheater heating coil sends its outlet air.

Field: Heating Source Object Type

This alpha field defines the source of superheated refrigerant gas from which the desuperheater heating coil recovers energy. Valid choices are:

```
Coil:Cooling:DX:SingleSpeed
Coil:Cooling:DX:TwoSpeed
Coil:Cooling:DX:TwoStageWithHumidityControlMode
Refrigeration:CompressorRack
Refrigeration:Condenser:AirCooled
Refrigeration:Condenser:EvaporativeCooled
Refrigeration:Condenser:WaterCooled
```

When the heating coil source is a DX Coil, the air loop's supply air fan control mode may be auto fan (cycling fan cycling coil), constant fan, or variable volume. When the heating source is a compressor rack for refrigerated cases or a refrigeration condenser, the supply air fan control mode should be either variable volume or constant fan.

NOTE: Use of the desuperheater heating coil in variable air volume systems should be done with caution since the model assumption of a fixed heat reclaim recovery efficiency may not be valid if the air flow rate over the coil varies significantly.

Field: Heating Source Name

This alpha field defines the name of the desuperheater heating coil source (e.g., the name of a specific valid coil (as mentioned in the previous field) which provides waste heat to this desuperheater heating coil).

NOTE: When the heating source is a Refrigeration Compressor rack, the heat rejection location in the Refrigeration:CompressorRack object must be "Outdoors". If the compressor rack heat rejection location is "Zone", the total amount of heat rejection available for reclaim (e.g., by this desuperheater heating coil) is set to zero by the compressor rack object and the simulation proceeds.

Field: Temperature Setpoint Node Name

This optional alpha field defines the name of the HVAC system node used for temperature-based control (e.g., controlling the heating coil's outlet air dry-bulb temperature to a setpoint). If the desuperheater heating coil is temperature controlled through the use of a Set Point Manager, then the control node specified in the Set Point Manager will be entered here. If the desuperheater heating coil is controlled based on a certain heating load to be met (e.g., using this heating coil as part of AirLoopHVAC:Unitary:Furnace:HeatCool for high humidity control), this field should be left blank.

Field: Parasitic Electric Load

This optional numeric field defines the parasitic electric load (in Watts) due to control valves or other devices specific to the desuperheater heating coil. The load is applied whenever the coil is heating the air. The model assumes that this electric load is small and does not contribute to heating the air.

Following is an example input for a desuperheater heating coil.

```

Coil:Heating:Desuperheater,
DesuperheaterCoil,           !- Coil Name
FanAndCoilAvailSched,        !- Availability Schedule
0.3,                         !- Heat Reclaim Recovery Efficiency
Cooling Coil Air Outlet Node, !- Coil Air Inlet Node Name
Air Loop Outlet Node,         !- Coil Air Outlet Node Name
Coil:Cooling:DX:SingleSpeed, !- Heating Source Type
Furnace ACDXCoil 1,          !- Heating Source Name
,                            !- Coil Temperature Setpoint Node Name

```

Coil:Heating:Desuperheater Outputs

```

HVAC,Average,Heating Coil Rate [W]
HVAC,Sum,Heating Coil Energy [J]
HVAC,Average,Heating Coil Electric Power [W]
HVAC,Sum,Heating Coil Electric Consumption [J]
HVAC,Average,Heating Coil Runtime Fraction

```

Heating Coil Rate [W]

This output is the average heating rate of the desuperheater heating coil in Watts over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

Heating Coil Energy [J]

This output is the total heating output of the desuperheater heating coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Report Meter).

Heating Coil Electric Power [W]

This output is the average electric consumption rate for the parasitic load associated with the desuperheater heating coil in Watts.

Heating Coil Electric Consumption [J]

This output is the electric consumption of the desuperheater heating coil parasitic load in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Runtime Fraction

This is the runtime fraction of the desuperheater heating coil for the timestep being reported. Since the desuperheater heating coil can only provide heat when the heat source object is active, the runtime fraction of the desuperheater heating coil will always be less than or equal to the runtime fraction of the heat source object.

Coil:Cooling:DX:VariableRefrigerantFlow

The variable refrigerant flow (VRF) DX cooling coil model is nearly identical to the single-speed DX cooling coil model (Ref. Coil:Cooling:DX:SingleSpeed). For this reason, an adaptation of the single-speed DX cooling coil model is used to model the variable-speed compression system used in VRF AC systems. The model inputs are quite similar to the input requirements for the single-speed DX cooling coil model, however, the location of a majority of the inputs have been moved to the variable refrigerant flow air conditioner object since multiple DX cooling coils will use the same DX compression system (Ref. AirConditioner:VariableRefrigerantFlow).

Field: Coil Name

This alpha field defines a unique user-assigned name for an instance of a VRF DX cooling coil. Any reference to this DX cooling coil by another object will use this name. This cooling coil name must be entered in the AirConditioner:VariableRefrigerantFlow object. No other system type uses this specific coil.

Field: Availability Schedule Name

This alpha field defines the name of the DX cooling coil availability schedule. Schedule values of 0 denote the DX cooling coil is off.

Field: Rated Total Cooling Capacity

This numeric field defines the rated total cooling capacity of the DX cooling coil. The total cooling capacity should be a “gross” value and not include thermal affects due to the supply air fan.

Field: Ratio Sensible Heat Ratio

This numeric field defines the sensible heat ratio (sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions. Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included)

Field: Rated Air Flow Rate

The air volume flow rate, in m^3 per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m^3/s and 0.00006041 m^3/s per watt of rated total cooling capacity (300 to 450 cfm/ton). The rated total cooling capacity and rated SHR should be performance information for the unit with at this rated air volume flow rate.

Field: Cooling Capacity Ratio Modifier Function of Temperature Curve Name

This alpha field defines the cooling capacity ratio modifier as a function of indoor wet-bulb temperature or indoor wet-bulb and outdoor dry-bulb temperatures. This curve is a linear, quadratic, or cubic curve if the cooling capacity is solely a function of indoor wet-bulb temperature (i.e., the indoor terminal units weighted average inlet air wet-bulb temperatures). Without specific manufacturers data indicating otherwise, the use of a single independent variable is recommended for this coil type. If, however, the user has reason to believe the cooling capacity is both a function of indoor wet-bulb temperature and outdoor dry-bulb temperature (and has manufacturers data to create the performance curve), a bi-quadratic equation using weighted average indoor wet-bulb temperature and condenser entering air dry-bulb temperature as the independent variables may be used. See the Engineering Reference for more discussion on using this input field.

Field: Cooling Capacity Modifier Curve Function of Flow Fraction Name

This alpha field defines the name of a linear, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Coil Air Inlet Node Name

This alpha field defines the name of the air inlet node entering the DX cooling coil.

Field: Coil Air Outlet Node Name

This alpha field defines the name of the air outlet node exiting the DX cooling coil.

Field: Name of Water Storage Tank for Condensate Collection

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Following is an example input for a Coil:Cooling:DX:VariableRefrigerantFlow object.

DX Coil Total Cooling Rate [W]

This field is the total (sensible and latent) cooling rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Cooling Energy [J]

This is the total (sensible plus latent) cooling output of the DX coil in Joules over the time step being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (Ref. Report Meter).

DX Coil Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Energy [J]

This is the moist air sensible cooling output of the DX coil in Joules for the time step being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Rate [W]

This is the latent cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Energy [J]

This is the latent cooling output of the DX coil in Joules for the time step being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Cooling Coil Runtime Fraction

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the time step being reported.

DX Cooling Coil Condensate Volumetric Flow Rate [m³/s]***DX Cooling Coil Condensate Volume [m³]***

These outputs are the rate and volume of water collected as condensate from the coil. These reports only appear if a water storage tank is named in the input object.

Coil:Heating:DX:VariableRefrigerantFlow

The variable refrigerant flow (VRF) DX heating coil model uses performance information at rated conditions along with performance curves for variations in total capacity, energy input ratio and part load fraction to determine performance at part-load conditions. The impacts of defrost operation is modeled based a combination of user inputs and empirical models taken from the air-to-air heat pump algorithms in DOE-2.1E.

The VRF DX heating coil input requires an availability schedule, the rated total heating capacity and the rated air volume flow rate. The rated air volume flow rate should be between 0.00008056 m³/s and 0.00002684 m³/s per watt of rated total heating capacity.

Two performance curves are required. The first performance curve defines the total heating capacity as a function of indoor air dry-bulb and outdoor condenser entering air wet-bulb temperature. This curve object is specified in the variable refrigerant flow air-to-air heat pump object. The second performance curve is specific to each VRF DX heating coil and defines the change in total heating capacity as a function of air flow fraction. Each of these performance curves are further discussed here.

1) Total heating capacity modifier curve (function of temperature, specified in Heat Pump)

The total heating capacity modifier curve (function of temperature) can be a function of both the outdoor wet-bulb temperature and indoor air dry-bulb temperature. Users have the choice of a bi-quadratic curve with two independent variables or a tri-quadratic curve with three independent variables. The tri-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the combined total capacity of all indoor units connected to the heat pump condenser and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature) and the combination ratio of the installed system.

2) Total heating capacity modifier curve (function of flow fraction, specified in DX coil)

The total heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating.

Field: Coil Name

This alpha field defines a unique user-assigned name for an instance of a VRF DX heating coil. Any reference to this DX heating coil by another object will use this name.

Field: Availability Schedule

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the DX heating coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Rated Total Heating Capacity

This numeric field defines the total, full load heating capacity in watts of the DX coil unit at rated conditions (outside air dry-bulb temperature of 8.33 C, outside air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field “rated air flow volume” below). The value entered here must be greater than 0. Capacity should not include supply air fan heat.

Field: Rated Air Flow Rate

This numeric field defines the volume air flow rate, in m^3 per second, across the DX heating coil at rated conditions. The value entered here must be greater than 0. The rated air volume flow rate should be between 0.00004027 m^3/s and 0.00006041 m^3/s per watt of rated total heating capacity. The rated total heating capacity and rated COP should be performance information for the unit with outside air dry-bulb temperature of 8.33 C, outside air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and the rated air volume flow rate defined here.

Field: Coil Air Inlet Node

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

Field: Coil Air Outlet Node

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

Field: Heating Capacity Ratio Modifier Function of Temperature Curve Name

This alpha field defines the heating capacity ratio modifier as a function of indoor dry-bulb temperature or indoor dry-bulb and outdoor wet-bulb temperatures. This curve is a linear, quadratic, or cubic curve if the heating capacity is solely a function of indoor dry-bulb temperature (i.e., the indoor terminal units weighted average inlet air dry-bulb temperatures). Without specific manufacturers data indicating otherwise, the use of a single independent variable is recommended for this coil type. If, however, the user has reason to believe the heating capacity is both a function of indoor dry-bulb temperature and outdoor wet-bulb temperature (and has manufacturers data to create the performance curve), a bi-quadratic equation using weighted average indoor dry-bulb temperature and condenser entering air wet-bulb temperature as the independent variables may be used. See the Engineering Reference for more discussion on using this input field.

Note: The choice of using either outdoor dry-bulb temperature or outdoor wet-bulb temperature as the independent variable in this performance curve is set in the parent object AirConditioner: VariableRefrigerantFlow.

Field: Heating Capacity Ratio Modifier Function of Flow Fraction Curve Name

This alpha field defines the name of a linear, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Following is an example input for the object.

```

```
HVAC,Average, DX Coil Total Heating Rate[W]
HVAC,Sum, DX Coil Total Heating Energy[J]
HVAC,Average, DX Cooling Coil Runtime Fraction
```

DX Coil Total Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Heating Energy[J]

This is the total heating output of the DX coil in Joules over the time step being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Report Meter).

DX Heating Coil Runtime Fraction

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the time step being reported.

Coil:Heating:Gas

The gas heating coil is a simple capacity model with a user inputted gas burner efficiency. The default for the gas burner efficiency is 80%. This coil will be simpler than shown in Figure 122 since it will only have air nodes to connect it in the system. The coil can be used in the air loop simulation or in the zone equipment as a reheat coil. Depending on where it is used determines if this coil is temperature or capacity controlled. If used in the air loop simulation it will be controlled to a specified temperature scheduled from the Setpoint Manager. If it is used in zone equipment, it will be controlled from the zone thermostat by meeting the zone demand.

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Gas Burner Efficiency

This is user inputted gas burner efficiency (decimal, not percent) and is defaulted to 80%.

Field: Nominal Capacity

This is the maximum capacity of the coil (W). This controlled coil will only provide the needed capacity to meet the control criteria whether it is temperature or capacity controlled. This field is autosizable.

Field: Air Inlet Node Name

The name of the air inlet to the gas coil, i.e. Heating Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the gas coil, i.e. Heating Coil Air Outlet Node.

Field: Temperature Setpoint Node Name

If the coil is used in the air loop simulation and is temperature controlled using a Set Point Manager, then the node that is the control node needs to be specified here. If the coil is used in an air terminal unit, the coil is load controlled and a control node set point is not required.

Field: Parasitic Electric Load

This is the parasitic electric load associated with the gas coil operation, such as an inducer fan, etc.. This will be modified by the PLR (or coil runtime fraction if a part-load fraction correlation is provided in the next input field) to reflect the time of operation in a simulation timestep.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of gas consumption rate by the heating coil as a function of the part load ratio (PLR, sensible heating load/nominal capacity of the heating coil). For any simulation timestep, the nominal gas consumption rate (heating load/burner efficiency) is divided by the part-load fraction (PLF) if a part-load curve has been defined. The part-load curve accounts for efficiency losses due to transient coil operation.

The part-load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the heating coil runs continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the heating coil is defined a PLR/PLF. If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional gas heating coil (e.g., residential furnace) would be:

$$PLF = 0.8 + 0.2(PLR)$$

Field: Parasitic Gas Load

This numeric field is the parasitic gas load associated with the gas coil's operation (Watts), such as a standing pilot light. The model assumes that this parasitic load is consumed only for the portion of the simulation timestep where the gas heating coil is not operating.

Coil:Heating:Gas Outputs

HVAC, Sum, Heating Coil Energy[J]
 HVAC, Average, Heating Coil Rate[W]
 HVAC, Sum, Heating Coil Gas Consumption [J]

HVAC,Average,Heating Coil Gas Consumption Rate [W]
HVAC,Sum,Heating Coil Electric Consumption [J]
HVAC,Average,Heating Coil Electric Power [W]
HVAC,Average,Heating Coil Runtime Fraction
HVAC,Sum,Heating Coil Parasitic Gas Consumption [J]
HVAC,Average,Heating Coil Parasitic Gas Consumption Rate [W]

Heating Coil Energy [J]

This field is the total heating output of the coil in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoils, Group Key = System (ref. Report Meter).

Heating Coil Rate [W]

This field is the average heating rate output of the coil in Watts over the timestep being reported.

Heating Coil Gas Consumption [J]

This field is the gas consumption of the heating coil in Joules over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified. This output is also added to a report meter with Resource Type = Gas, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Gas Consumption Rate [W]

This field is the average gas consumption rate of the coil in Watts over the timestep being reported, including the impacts of part-load performance if a part load fraction correlation is specified.

Heating Coil Electric Consumption [J]

This field is the electric consumption of the heating coil auxiliaries in Joules over the timestep being reported (e.g., inducer fan). This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Electric Power [W]

This field is the average electric consumption rate of the heating coil auxiliaries (e.g., inducer fan) in Watts over the timestep being reported.

Heating Coil Parasitic Gas Consumption [J]

This field is the parasitic gas consumption of the heating coil in Joules over the timestep being reported (e.g., standing pilot light). The model assumes that the parasitic load is accumulated only for the portion of the simulation timestep where the gas heating coil is not operating. This output is also added to a report meter with Resource Type = Gas, End Use Key = Heating, Group Key = System (ref. Report Meter).

Heating Coil Parasitic Gas Consumption Rate [W]

This field is the average parasitic gas consumption rate of the heating coil (e.g., standing pilot light) in Watts over the timestep being reported. The model assumes that the parasitic load is present only for the portion of the simulation timestep where the gas heating coil is not operating.

Coil:Cooling:Water:DetailedGeometry

This detailed flat fin coil model is for continuous plate fins. First, found in Type 12 from MODSIM, but now programmed directly from Elmahdy, A.H. and Mitalas, G.P. Then there was a discontinuity in their original model that was fixed in the EnergyPlus implementation. Now this model can be used in an interval halving solution technique for controlling this coil without the problems of non-convergence.

"A Model for Cooling and Dehumidifying Coils for Use in Energy Requirements for Buildings" ASHRAE Transactions, Vol. 83, Part 2, pp. 103-117 (1977). For fin efficiency see K.A. Gardner, "Efficiency of Extended ,," Transactions ASME, Vol. 67, pp. 621-631, 1945.

The following figures illustrate the geometry and circuits in a cooling coil.

Figure 123. Geometry of a Cooling Coil (CC)

Figure 124. Number of Coolant Circuits (CCNCC)

Field: Name

A unique identifying name for each coil.

Field: Available Schedule Name

Schedule that defines when the coil is available.

Field: Maximum Water Flow Rate

The maximum possible water flow rate (m^3/sec) through the coil.

Field: Tube Outside Surface Area

The outside surface area (m^2) of the tubes that is exposed to air (i.e. the outside area of the unfinned tubes minus the area of tubes covered by the fins).

Field: Total Tube Inside Area

The total surface area (m^2) inside the tubes (water side).

Field: Fin Surface Area

The total surface area (m^2) of the fins attached to the coil.

Field: Minimum Air Flow Area

The minimum cross sectional area (m^2) available for air passage. Frequently calculated as

$$A_{\min} = (A_{\min}/A_{fr}) * A_{fr}$$

where A_{fr} is the frontal area of the heat exchanger, and (A_{\min}/A_{fr}) is the ratio of the minimum airflow area to frontal area.

Field: Coil Depth

The distance (m) from the front of the coil to the back of the coil in the airflow direction. Also called the fin depth. Illustrated in the figure (Figure 123. Geometry of a Cooling Coil (CC)).

Field: Fin Diameter

The outside diameter (m) of the fins. Used instead of COIL HEIGHT

Field: Fin Thickness

Thickness (m) of the air side fins.

Field: Tube Inside Diameter

The inside diameter (m) of the tubes.

Field: Tube Outside Diameter

The outside diameter (m) of the tubes.

Field: Tube Thermal Conductivity

The thermal conductivity (W/m-K) of the tube material.

Field: Fin Thermal Conductivity

The thermal conductivity (W/m-K) of the fin material.

Field: Fin Spacing

The spacing (m) of the fins, centerline to centerline.

Field: Tube Depth Spacing

The spacing (m) of the tube rows, centerline to centerline. Also called tube longitudinal spacing.

Field: Number of Tube Rows

The number of tube rows in the direction of the airflow.

Field: Number of Tubes per Row

The number of tubes per row. (NTPR in the above diagram)

Field: Water Inlet Node Name

The name of the water coil inlet from the chilled water loop, i.e. Cooling Coil Water Inlet Node.

Field: Water Outlet Node Name

The name of the water coil outlet from the chilled water loop, i.e. Cooling Coil Water Outlet Node.

Field: Air Inlet Node Name

The name of the air inlet to the water coil, i.e. Cooling Coil Air Inlet Node.

Field: Air Outlet Node Name

The name of the air outlet from the water coil, i.e. Cooling Coil Air Outlet Node.

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Examples of these statements in an IDF are:

Coil:Cooling:Water:DetailedGeometry Outputs

HVAC,Sum,Total Water Cooling Coil Energy[J]
HVAC,Sum,Sensible Water Cooling Coil Energy[J]
HVAC,Average,Total Water Cooling Coil Rate[W]
HVAC,Average,Sensible Water Cooling Coil Rate[W]
HVAC,Average,Cooling Coil Condensate Volumetric Flow Rate [m3/s]
Zone,Meter,OnSiteWater:Facility [m3]
Zone,Meter,OnSiteWater:HVAC [m3]
Zone,Meter,Condensate:OnSiteWater [m3]
HVAC,Sum,Cooling Coil Condensate Volume [m3]

Total Water Cooling Coil Energy (J)

Total Water Cooling Coil Energy is the total amount of heat transfer taking place in the coil at the operating conditions.

Sensible Water Cooling Coil Energy (J)

Sensible Water Cooling Coil Energy is the total amount of Sensible heat transfer taking place in the coil at the operating conditions. It only takes into account temperature difference in the inlet and outlet air streams at operating conditions.

Total Water Cooling Coil Rate (W)

Total Water Cooling Coil Rate is the Rate of heat transfer taking place in the coil at the operating conditions. The units are (J/sec) or Watts.

Sensible Water Cooling Coil Rate (W)

Sensible Water Cooling Coil Rate is the Rate of Sensible heat transfer taking place in the coil at the operating conditions.

In addition, if a Water Storage Tank is used to collect coil condensate, then the following outputs will be available.

Cooling Coil Condensate Volumetric Flow Rate [m³/s]**Cooling Coil Condensate Volume [m³]**

These reports provide the rate and amount of condensate from the coil. Condensate is water condensed out of the air as a result of cooling. The condensate volume is also reported on the meter for "OnSiteWater."

Coil:Cooling:DX:SingleSpeed

This DX cooling coil model and input are quite different from that for the heating and cooling water coils. The simple water coils use an NTU-effectiveness heat exchanger model. The single speed DX coil model uses performance information at rated conditions along with curve fits for variations in total capacity, energy input ratio and part-load fraction to determine performance at part-load conditions. Sensible/latent capacity splits are determined by the rated sensible heat ratio (SHR) and the apparatus dewpoint/bypass factor (ADP/BF) approach. This approach is analogous to the NTU-effectiveness calculations used for sensible-only heat exchanger calculations, extended to a cooling and dehumidifying coil.

This DX cooling coil input requires an availability schedule, the rated total cooling capacity, the rated SHR, the rated COP, and the rated air volume flow rate. The latter 4 inputs determine the coil performance at the rating point (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb and air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb). The rated air volume flow rate should be between .00004027 m³/s and .00006041 m³/s per watt of rated total cooling capacity (300 to 450 cfm/ton).

This model requires 5 curves as follows:

1. The total cooling capacity modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
2. The total cooling capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity

- modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating.
3. The energy input ratio (EIR) modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
 4. The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
 5. The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible cooling load / steady-state sensible cooling capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The curve should be normalized to a value of 1.0 when the part-load ratio equals 1.0 (i.e., the compressor(s) run continuously for the simulation timestep).

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (see Performance Curves in this document).

The next four input fields are optional and relate to the degradation of latent cooling capacity when the supply air fan operates continuously while the cooling coil/compressor cycle on and off to meet the cooling load. The fan operating mode is determined in the parent object and is considered to either be constant (e.g. CoilSystem:Cooling:DX) or can be scheduled (e.g. AirLoopHVAC:UnitaryHeatCool). When scheduled, the schedule value must be greater than 0 to calculate degradation of latent cooling capacity. At times when the parent object's supply air fan operating mode schedule is 0, latent degradation will be ignored. When modeling latent capacity degradation, these next four input fields must all have positive values.

The next input specifies the outdoor air node used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor temperature entering the condenser is taken directly from the weather data. If this field is not blank, the node name specified must be listed in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an OutdoorAir:NodeList object where the outdoor temperature entering the condenser is taken directly from the weather data.

The next input describes the type of outdoor condenser coil used with the DX cooling coil (Air Cooled or Evap Cooled). The following three inputs are required when modeling an evaporative-cooled condenser: evaporative condenser effectiveness, evaporative condenser air volume flow rate, and the power consumed by the evaporative condenser pump. Crankcase heater capacity and cutout temperature are entered in the next two input fields. The final two fields for this object define the name of the water storage tank for supply and condensate collection. See section “DX Cooling Coil Model” in the EnergyPlus Engineering Document for further details regarding this model.

Field: Name

A unique user-assigned name for an instance of a DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

Field: Rated Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb⁹, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included). When used in a heat pump, the rated total cooling capacity should be within 20% of the rated total heating capacity, otherwise a warning message is issued.

Field: Rated Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated COP

The coefficient of performance (cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity (gross)”. If this input field is left blank, the default value is 3.0.

Field: Rated Air Flow Rate

The air volume flow rate, in m³ per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total cooling capacity (300 to 450 cfm/ton). The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Rated Evaporator Fan Power Per Volume Flow Rate

This field is the electric power for the evaporator (cooling coil) fan per air volume flow rate through the coil at the rated conditions in W/(m³/s). The default value is 773.3 W/(m³/s) (365 W/1000 cfm) if this field is left blank. If a value is entered, it must be >= 0.0 and <= 1250 W/(m³/s). This value is only used to calculate Seasonal Energy Efficiency Ratio (SEER), Energy Efficiency Ratio (EER), Integrated Energy Efficiency Ratio (IEER) and the Standard Rating (Net) Cooling Capacity which will be outputs in the EnergyPlus eio file (ref. EnergyPlus Engineering Reference, Single Speed DX Cooling Coil, Standard Ratings). This value is not used for modeling the evaporator (cooling coil) fan during simulations; instead, it is used for calculating SEER, EER, IEER and Standard Rating Cooling Capacity to assist the user in verifying their inputs for modeling this type of equipment.

⁹ The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

Field: Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

The name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$PLF \geq 0.7$ and $PLF \geq PLR$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Nominal Time for Condensate Removal to Begin

The nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other "parent" objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]), and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

Ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other "parent" objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]); and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation.

Field: Maximum Cycling Rate

The maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other "parent" objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]); and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation.

Field: Latent Capacity Time Constant

Time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45: supply air fan operating mode must be continuous. That is, the supply air fan operating mode may be specified in other "parent" objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects (e.g., AirloopHVAC:UnitaryHeatCool), and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is AirCooled.

Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: Evaporative Condenser Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m^3/s per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = Air Cooled.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field "Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation" (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump (Ref. AirLoopHVAC:UnitaryHeatPump:AirToAir or PackageTerminal: HeatPump:AirToAir), the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. Coil:Heating:DX:SingleSpeed) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C, and the default value is 10°C.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling of its condenser. If blank or omitted, then the unit will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the unit will obtain its water from that tank. If a tank is specified, the unit will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the condenser needs, then the unit will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Field: Basin Heater Capacity

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature ($^{\circ}\text{C}$) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2°C , and the default value is 2°C if this field is left blank.

Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

Following is an example input for a Coil:Cooling:DX:SingleSpeed coil.

```

Coil:Cooling:DX:TwoSpeed

This component models a two-speed (or variable speed) DX compressor and fan. The method is based on the model used for the cycling, single speed DX unit. The single speed unit is described by single full load capacity, SHR, COP, and air flow rate at rated conditions. Off rated full load performance is obtained by the use of 4 modifier curves. At partial load the unit cycles on/off and the cycling losses are described by a part load fraction curve.

The multispeed unit is described by specifying the performance at two states: high speed compressor, high speed fan; and low speed compressor, low speed fan. When the unit load is above the high speed capacity, the unit runs with high speed compressor and fan. When the load on the unit is below the high speed capacity but above the low speed capacity, the unit will run with performance intermediate between high speed and low speed. When the load is less than the low speed capacity, the unit will cycle on/off just like the single speed unit.

The multispeed unit model requires 2 full sets of performance data. There must be a high and low speed capacity, SHR, COP, and evaporator air flow rate; as well as high and low speed performance curves – total cooling capacity modifier curve (function of temperature) and energy input ratio modifier curve (function of temperature).

The multispeed DX component should be used for all cases in which a DX VAV system is being simulated. Obviously this model – in which performance is obtained by interpolating between 2 specified states - is an oversimplification of how real multi-speed and variable speed DX cooling units are controlled. But detailed descriptions of how actual units perform and are controlled are not available. This model should give a good average prediction of multispeed and variable speed DX cooling unit performance.

Field: Name

A unique user-assigned name for an instance of a multispeed DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Rated High Speed Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated High Speed Sensible Heat Ratio

The sensible heat ratio (sensible capacity divided by total cooling capacity) of the DX cooling coil for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb¹⁰, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb¹⁰, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated High Speed COP

The coefficient of performance (cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit for high speed compressor and high speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity (gross)”. If this input field is left blank, the default value is 3.0.

Field: Rated High Speed Air Flow Rate

The high speed air volume flow rate, in m³ per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total cooling capacity. The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

¹⁰ The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

Field: Unit Internal Static Air Pressure

If this coil is used with a Fan:VariableVolume to model a packaged variable-air-volume unit, then ratings for standard rated net capacity, EER, and IEER will be calculated per ANSI/AHRI Standard 340/360-2007 with Addenda 1 and 2. This field is to specify the internal static air pressure, in units of Pascals, associated with the unit's supply air flow for rating purposes. This field does not affect the performance during operation. This field is optional. If this field is used, then the internal static air pressure is used with the associated fan characteristics when calculating standard rated net capacity, EER, and IEER. If this field is not used, then the standard ratings are still performed but use a default for specific fan power of 773.3 (W/(m³/s)). The air pressure drop/rise input here should be "internal" in the sense that it is for the entire package of unitary equipment as it would be tested in a laboratory (including other non-cooling sections inside the package for filters, dampers, and/or heating coils) but none of the "external" pressure drop for distributing supply air throughout the building. This is different from the input field called Pressure Rise in the fan object which includes both the external static pressure and the internal static pressure. The results of standard rating calculations are reported to the EIO file and to predefined output tables called "DX Cooling Coils" and "VAV DX Cooling Standard Rating Details."

Field: Air Inlet Node

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point. This curve is used for performance at the high speed compressor, high speed fan operating point.

Field: Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate. This curve is applied only at the high speed compressor, high speed fan operating point. There is no corresponding curve for the low speed operating point.

Field: Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point. This curve is used for performance at the high speed compressor, high speed fan operating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

The name of a quadratic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate. This curve is applied only at the high speed compressor, high speed fan operating point. There is no corresponding curve for the low speed operating point.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Rated Low Speed Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate, low speed” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated Low Speed Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate, low speed” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated Low Speed COP

The coefficient of performance (COP=cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit for low speed compressor and low speed fan at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering

the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate, low speed” below). The input power includes power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity (gross)”. If this input field is left blank, the default value is 3.0.

Field: Rated Low Speed Air Flow Rate

The low speed volume air flow rate, in m^3 per second, across the DX cooling coil at rated conditions. The rated air volume flow rate should be between 0.00004027 m^3/s and 0.00006041 m^3/s per watt of rated total cooling capacity. The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Low Speed Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point. This curve is used for performance at the low speed compressor, low speed fan operating point.

Field: Low Speed Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wetbulb temperature of the air entering the cooling coil and the drybulb temperature of the air entering the air-cooled condenser (wetbulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point. This curve is used for performance at the low speed compressor, low speed fan operating point.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the multi-speed DX cooling coil. Valid choices for this input field are Air Cooled or Evap Cooled. The default for this field is Air Cooled.

Field: High Speed Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at high compressor/fan speed, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,\ o}) + (1 - EvapCondEffectiveness_{HighSpeed})(T_{db,\ o} - T_{wb,\ o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,\ o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,\ o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: High Speed Evaporative Condenser Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser at high compressor/fan speed. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m^3/s per watt of rated high-speed total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: High Speed Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts at high compressor/fan speed. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated high-speed total cooling capacity). This field is not used when Condenser Type = Air Cooled.

Field: Low Speed Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at low compressor/fan speed, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,\ o}) + (1 - EvapCondEffectiveness_{LowSpeed})(T_{db,\ o} - T_{wb,\ o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,\ o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,\ o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve, low speed (function of temperature) and the Energy Input Ratio Modifier Curve, low speed (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled. See field "Evaporative Condenser Effectiveness, High Speed" above for further information.

Field: Low Speed Evaporative Condenser Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser at low compressor/fan speed. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000048 m^3/s per watt of rated high-speed total cooling capacity [280 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: Low Speed Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts at low compressor/fan speed. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.001422 W per watt [5 W/ton] of rated high-speed total capacity). This field is not used when Condenser Type = Air Cooled.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Field: Basin Heater Capacity

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

Following is an example input for the object.

```
Coil:Cooling:DX:TwoSpeed,
  Main Cooling Coil 1,           !- Name

Coil:Cooling:DX:TwoStageWithHumidityControlMode

The multimode DX coil is functionally equivalent to Coil:Cooling:DX:SingleSpeed but with multiple performance modes. It is capable of modeling two-stage DX units and units with an enhanced dehumidification mode such as coil bypass or subcool reheat. This object contains one-time specifications for the DX unit such as node names and crankcase heater specifications. It references one or more CoilPerformance:DX:Cooling objects which define the performance for each mode of operation. It can have up to 4 performance modes to accommodate a 2-stage 2-mode unit.

The multimode DX coil can be used only as a component of CoilSystem:Cooling:DX or AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass (parent object). These parent objects pass a load and dehumidification mode to this coil. If the coil has 2 capacity stages, the multimode coil model determines the stage sequencing.

Field: Name

A unique user-assigned name for an instance of a DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during a given time period. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off.

Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field “Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation” (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump (Ref. AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass), the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. Coil:Heating:DX:SingleSpeed) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor’s crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C, and the default value is 10°C.

Field: Number of Capacity Stages

This integer field defines the number of capacity stages. The value for this input field must be either 1 or 2, and the default value is 1. Larger DX units often have two capacity stages, which are often two completely independent compressor/coil circuits with the evaporator coils arranged in parallel in the supply air stream. 2-stage operation affects cycling losses and latent degradation due to re-evaporation of moisture with continuous fan operation.

Field: Number of Enhanced Dehumidification Modes

This integer field defines the number of enhanced dehumidification modes available. The value for this input field must be 0 or 1, and the default value is 0. If the DX unit can switch operating modes to increase dehumidification based on a humidistat signal, then set this to 1. This field just specifies the availability of enhanced dehumidification. Actual control of the operating mode is handled by the coil’s parent component.

Field: Normal Mode Stage 1 Coil Performance Object Type**Field: Normal Mode Stage 1 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1 operation without enhanced dehumidification (normal mode). The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Normal Mode Stage 1+2 Coil Performance Object Type**Field: Normal Mode Stage 1+2 Coil Performance Object Name**

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1+2 operation (both stages active) without

enhanced dehumidification (normal mode). The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Dehumidification Mode 1 Stage 1 Coil Performance Object Type

Field: Dehumidification Mode 1 Stage 1 Coil Performance Object Name

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1 operation with enhanced dehumidification active. The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Dehumidification Mode 1 Stage 1+2 Coil Performance Object Type

Field: Dehumidification Mode 1 Stage 1+2 Coil Performance Object Name

This pair of fields specifies the object type and name for the coil performance object which specifies the DX coil performance for stage 1+2 operation (both stages active) with enhanced dehumidification active. The only valid performance object type is CoilPerformance:DX:Cooling.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the cooler will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Field: Basin Heater Capacity

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the

simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

Coil:Cooling:DX:MultiSpeed

This component models a DX cooling unit with multiple discrete levels of cooling capacity. Depending on input choices, the user can model a single compressor with multiple operating speeds, or a unit with a single cooling coil fed by multiple compressors (e.g., row split or intertwined coil circuiting). Currently, this cooling coil can only be referenced by a AirLoopHVAC:UnitaryHeatPump:AirToAir:Multispeed object. Refer to Coil:Cooling:DX:TwoStageWithHumidityControlMode if the user wishes to model a cooling coil with discrete levels of cooling and the possibility of air bypass during low speed operation (e.g. face-split coil circuiting), or if cooling coil operation based on dehumidification requirements is desired.

The multispeed DX cooling coil can have from two to four operating speeds. When the coil operates at Speed 1 (the lowest speed), its performance is very similar to the single speed DX coil where the impacts of part-load ratio and latent capacity degradation can be included. When the coil operates at higher speeds (above Speed 1), the linear approximation methodology is applied. The coil outputs at two consecutive speeds are linearly interpolated to meet the required cooling capacity during an HVAC system timestep. When the coil performs above the lowest speed, the user can chose if they want to include part-load ratio and latent capacity degradation impacts at the higher speeds.

The multispeed unit is described by specifying the performance at different operating speeds. Each speed has its own set of input specifications: full load capacity, SHR, COP and air flow rate at rated conditions, along with modifier curves to determine performance when actual operating conditions are different from the rated conditions.

The coil operates to meet the sensible capacity being requested. When this requested capacity is above the sensible capacity of the highest operating speed, the coil runs continuously at the highest speed. When the requested capacity is between the sensible capacities of two consecutive speeds, the unit will operate a portion of the time at each speed to meet the request. When the requested capacity is less than the low speed (Speed 1) capacity, the unit will cycle on/off as needed.

Field: Name

A unique user-assigned name for an instance of a multispeed DX cooling coil. Any reference to this DX coil by another object will use this name.

Field: Availability Schedule Name

The name of the schedule (ref: Schedule) that denotes whether the DX cooling coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node Name

The name of the HVAC system node from which the DX cooling coil draws its inlet air.

Field: Air Outlet Node Name

The name of the HVAC system node to which the DX cooling coil sends its outlet air.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air

temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the multispeed DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling. If blank or omitted, then the evaporative cooler will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, then the cooler will obtain its water from that tank. If a tank is specified, the coil will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the cooler needs, then the cooler will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Field: Apply Part Load Fraction to Speeds Greater than 1

This field determines whether part-load impacts on coil energy use are applied when the coil is operating at speeds greater than speed 1. The allowed choices are Yes or No, with the default being No if this field is left blank. Other input fields in this object allow the user to specify a part-load fraction correlation for each speed to account for compressor start up losses (cycle on/off). For the case of a single multi-speed compressor, the part load losses may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify NO for this input field to neglect part-load impacts on energy use at higher operating speeds. If part-load impacts on coil energy use are thought to be significant (e.g., intertwined cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify YES and the part-load fraction correlations specified for speeds 2 through 4 will be applied as appropriate. The selection for this input field does not affect part-load impacts when the compressor cycles between speed 1 and off (i.e., the part-load fraction correlation for speed 1 is always applied).

Field: Apply Latent Degradation to Speeds Greater than 1

This field determines whether latent capacity degradation is applied when the coil is operating at speeds greater than speed 1. The allowed choices are Yes or No, with the default being No if this field is left blank. Other input fields in this object allow the user to specify latent capacity degradation at each speed.

The latent capacity degradation model only applies when the ContinuousFanWithCyclingCompressor supply air fan operating mode is specified, to account for moisture evaporation from the wet cooling coil when the compressor cycles off but the supply air fan continues to operate. For the case of a single multi-speed compressor, latent capacity degradation may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify NO for this input field to neglect latent capacity degradation impacts at higher operating speeds. If latent capacity degradation is thought to be significant (e.g., intertwined or row-split cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify YES and the latent capacity degradation model will be applied

for speeds 2 through 4 as appropriate. The selection for this input field does not affect latent capacity degradation between speed 1 and off.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field “Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation” (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor’s crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C. If this input field is left blank, the default value is 10°C.

Field: Basin Heater Capacity

This numeric field contains the capacity of the DX coil’s electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

Field: Fuel Type

This alpha field determines the type of fuel that this cooling coil uses. This field has seven choices: Electricity, NaturalGas, PropaneGas, Diesel, Gasoline, FuelOil#1, and FuelOil#2. The default is NaturalGas.

Field: Number of Speeds

This field specifies the number of sets of data being entered for rated specifications, performance curves, evaporative condenser data, latent degradation data, and waste heat specifications for each cooling speed. The rated specifications consist of rated capacity, rated SHR, rated COP, and rated air flow rate. The performance curves consist of a total capacity modifier curve as a function of temperature, total capacity modifier curve as a function of flow fraction, energy input ratio modifier curve as a function of temperature, energy input ratio

modifier curve as a function of flow fraction, and part load fraction correlation as a function of part load ratio. The evaporative condenser data consists of effectiveness, condenser air volume flow rate, and rated pump power consumption. The latent degradation data consists of nominal time for condensate removal to begin, ratio of initial moisture evaporation rate and steady-state latent capacity, maximum On/Off cycling rate, and latent capacity time constant. The latent degradation data are only applied if the supply air fan operation mode is specified as ContinuousFanWithCyclingCompressor. The waste heat specifications include the fraction of energy input to the cooling coil at the fully loaded and rated conditions, and a temperature modifier. The minimum number of speeds for cooling is 2 and the maximum number is 4. The number of speeds should be the same as the number of speeds for cooling defined in its parent object (AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed). The first set of performance inputs is for Speed 1 and should be for low speed, and the last set of performance inputs should be for high speed. For example, if only three cooling speeds are defined, the first set should be for low speed (Speed 1), the second set should be for medium speed (Speed 2), and the third set should be for high speed (Speed 3). In this example, any performance inputs for Speed 4 would be neglected (since this input field specifies that the coil only has three cooling speeds).

Field Group: rated specification, performance curves, latent capacity degradation inputs, and evaporative cooled condenser data

The performance for each cooling speed must be specified as shown below. All inputs for Speed 1 are required first, followed by the inputs for Speed 2, Speed 3 and Speed 4.

Field: Speed <x> Rated Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb¹¹, and a cooling coil air flow rate defined by field “Rated Air Volume Flow Rate, Speed <x>” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Speed <x> Rated Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “Rated Air Volume Flow Rate, Speed <x>” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Speed <x> Rated COP

The coefficient of performance (COP=cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit for Speed <x> operation at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “Rated Air Volume Flow Rate, Speed <x>” below). The input power includes power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field “Rated Total Cooling Capacity, Speed <x> (gross)”. If this input field is left blank, the default value is 3.0.

Field: Speed <x> Rated Air Flow Rate

The volumetric air flow rate for Speed <x>, in m³ per second, across the DX cooling coil at rated conditions. The rated air volume flow rate for Speed <x> should be between 0.00004027 m³/s and 0.00006041 m³/s per watt of rated total cooling capacity for Speed <x>. The rated total cooling capacity, rated SHR and rated COP for Speed <x> should be performance information for the unit with air entering the cooling coil at 26.7°C

¹¹ The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Speed <x> Rated Evaporator Fan Power Per Volume Flow Rate

This field is the electric power for the evaporator (cooling coil) fan per air volume flow rate through the coil at the rated conditions for Speed <x> in W/(m³/s). The default value is 773.3 W/(m³/s) (365 W/1000 cfm) if this field is left blank. If a value is entered, it must be ≥ 0.0 and ≤ 1250 W/(m³/s). This value is only used to calculate Seasonal Energy Efficiency Ratio (SEER), and the Standard Rating (Net) Cooling Capacity which will be outputs in the EnergyPlus eio file (ref. EnergyPlus Engineering Reference, Multi-Speed DX Cooling Coil, Standard Ratings). This value is not used for modeling the evaporator (cooling coil) fan during simulations; instead, it is used for calculating SEER and Standard Rating Cooling Capacity to assist the user in verifying their inputs for modeling this type of equipment.

Field: Speed <x> Total Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity for Speed <x> as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity for Speed <x> to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity for Speed <x> as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate for Speed <x> (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity for Speed <x> at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate for Speed <x>.

Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) for Speed <x> as a function of the wetbulb temperature of the air entering the cooling coil and the drybulb temperature of the air entering the air-cooled condenser (wetbulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR for Speed <x> (inverse of rated COP for Speed <x>) to give the EIR for Speed <x> at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point.

Field: Speed <x> Energy Input Ratio Function of Flow Fraction Curve Name

The name of a quadratic performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) for Speed <x> as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate for Speed <x> (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR for Speed <x> at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate for Speed <x>.

Field: Speed <x> Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity for Speed <x>). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep for Speed <x>. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional DX cooling coil (Speed <x>) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Speed <x> Nominal Time for Condensate Removal to Begin

For Speed <x>, the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other “parent” objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]), and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

For Speed <x>, the ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) for Speed <x> at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other “parent” objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]); and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Maximum Cycling Rate

For Speed <x>, the maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other “parent” objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be

scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]); and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Latent Capacity Time Constant

For Speed <x>, the time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other "parent" objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]), and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation for Speed <x>.

Field: Speed <x> Rated Waste Heat Fraction of Power Input

The fraction of energy input to the cooling coil that is available as recoverable waste heat at full load and rated conditions for Speed <x>.

Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of outdoor dry-bulb temperature and the entering coil dry-bulb temperature at Speed <x>. The output of this curve is multiplied by the rated waste heat fraction at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point. When the fuel type is electricity, this field can remain blank since it is ignored by the program in this instance.

Field: Speed <x> Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser at Speed <x>, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,\ o}) + (1 - EvapCondEffectiveness_{Speed1})(T_{db,\ o} - T_{wb,\ o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,\ o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,\ o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference

performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve, Speed <x> (function of temperature) and the Energy Input Ratio Modifier Curve, Speed <x> (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves for Speed <x> must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: Speed <x> Evaporative Condenser Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser at Speed <x>. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000114 m^3/s per watt of rated total cooling capacity for Speed <x> [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: Speed <x> Rated Evaporative Condenser Pump Power Consumption

The rated power of the evaporative condenser water pump in Watts at Speed <x>. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total capacity for Speed <x>). This field is not used when Condenser Type = Air Cooled.

Following is an example input for this multispeed DX cooling coil.

DX Coil Total Cooling Rate [W]

This field is the total (sensible and latent) cooling rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Cooling Energy [J]

This is the total (sensible plus latent) cooling output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (Ref. Report Meter).

DX Coil Sensible Cooling Rate [W]

This output is the moist air sensible cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Energy [J]

This is the moist air sensible cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Rate [W]

This is the latent cooling rate output of the DX coil in Watts. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Energy [J]

This is the latent cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Cooling Coil Electric Power [W]

This output is the electricity consumption rate of the DX coil compressor and condenser fan(s) in Watts. This value is calculated for each HVAC system timestep, and the results are averaged for the timestep being reported.

DX Cooling Coil Electric Consumption [J]

This is the electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (Ref. Report Meter).

DX Cooling Coil Runtime Fraction

This is the runtime fraction of the DX coil compressor and condenser fan(s) for the timestep being reported.

DX Cooling Coil Crankcase Heater Power[W]

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. If the DX Cooling Coil is used in a heat pump, the crankcase heater is reported only for the heating coil.

DX Cooling Coil Crankcase Heater Consumption[J]

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter). This output variable appears only when the DX Cooling Coil is not used as part of a heat pump, otherwise the crankcase heater is reported only for the heating coil.

Cooling Coil Condenser Inlet Temp [C]

This is the inlet air temperature to the condenser coil in degrees C. This value can represent the outdoor air dry-bulb temperature, wet-bulb temperature, or somewhere in between from the weather data being used, depending on the value used in the input field "Evaporative Condenser Effectiveness". The temperature reported here is used in the various modifier curves related to temperature (e.g., Total Cooling Capacity Modifier Curve [function of temperature]). This output variable appears only when the DX Cooling Coil is not used as part of a heat pump, otherwise the crankcase heater is reported only for the heating coil.

DX Cooling Coil Evap Condenser Water Consumption [m3]

This output is the amount of water used to evaporatively cool the condenser coil inlet air, in cubic meters. This output is also added to a report meter with Resource Type = Water, End Use Key = Cooling, Group Key = System (ref. Report Meter). This output variable appears only when the DX Cooling Coil is evaporatively cooled.

DX Cooling Coil Evap Condenser Pump Electric Power [W]

This is the average electricity consumption rate of the evaporative condenser water pump in Watts for the timestep being reported. This output variable appears only when the DX Cooling Coil is evaporatively cooled.

DX Cooling Coil Evap Condenser Pump Electric Consumption [J]

This is the electricity consumption rate of the evaporative condenser water pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter). This output variable appears only when the DX Cooling Coil is evaporatively cooled.

DX Cooling Coil Stage 2 Runtime Fraction

This is the runtime fraction of the stage 2 DX coil compressor and condenser fan(s) for the timestep being reported. Applicable only for COIL:Coil:Cooling:DX:TwoStageWithHumidityControlMode when 2 capacity stages are specified. For 2-stage systems, DX Cooling Coil Runtime Fraction is the stage 1 runtime fraction. These runtime fractions overlap, because stage 2 will not run unless stage 1 is already running. For example, a system where stage 1 is 60% of total capacity is passed a load of 70%. The DX Cooling Coil Runtime Fraction (stage 1) will be 1.0, and the DX Cooling Coil Stage 2 Runtime Fraction will be 0.25 [(70%-60%)/(100%-60%)].

DX Cooling Coil Dehumidification Mode

This is the dehumidification mode for the timestep being reported. Applicable only for COIL:Coil:Cooling:DX:TwoStageWithHumidityControlMode when enhanced dehumidification mode

is available. A value of 0 indicates normal mode (extra dehumidification not active). A value of 1 indicates dehumidification mode 1 is active. Note that this is an averaged variable, so fractional values are likely to be reported for reporting frequencies longer than "detailed".

DX Cooling Coil Condensate Volumetric Flow Rate [m3/s]

DX Cooling Coil Condensate Volume [m3]

These outputs are the rate and volume of water collected as condensate from the coil. These reports only appear if a water storage tank is named in the input object.

Mains Water Supply for DX Cooling Coil Evap Condenser [m3]

This is the water consumed by the DX Cooling Coil evaporatively cooled condenser that is met by the mains water. This output variable appears only when the DX Cooling Coil is evaporatively cooled.

DX Cooling Coil Basin Heater Electric Power [W]

This is the average electricity consumption rate of the basin heater in Watts for the timestep being reported. This output variable appears only when the DX Cooling Coil is evaporatively cooled and the Basin Heater Capacity is greater than 0.

DX Cooling Coil Basin Heater Electric Consumption [J]

This is the electricity consumption rate of the basin heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter). This output variable appears only when the DX Cooling Coil is evaporatively cooled and the Basin Heater Capacity is greater than 0.

DX Cooling Coil <Fuel Type> Power [W]

This output variable appears only when using the Coil:Cooling:DX:Multispeed object and a fuel type other than electricity is used. This variable describes the input fuel type power for the cooling coil in Watts, averaged during the timestep being reported.

DX Cooling Coil <Fuel Type> Consumption [J]

This output variable appears only when using the Coil:Cooling:DX:Multispeed object and a fuel type other than electricity is used. This variable describes the input fuel type consumption for the multispeed cooling coil in the unit of Joules, summed for the timestep being reported. The electric consumption is excluded..This output is added to a report meter with Resource Type = <Fuel Type>, End Use Key = Cooling, Group Key = System (ref. Report Meter).

Note: <Fuel Type> in the above two output variables depends on the user specified input for the Fuel Type field. In addition to Electricity, valid fuel types are NaturalGas, Propane, FuelOil#1, FuelOil#2, Coal, Diesel, and Gasoline.

Coil:Cooling:DX:VariableSpeed

The Variable-Speed DX Cooling Coil is a collection of performance curves that represent the cooling coil at various speed levels. The performance curves should be generated from a Reference Unit data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. On the other hand, the model uses the bypass factor approach to calculate sensible heat transfer rate, similar to the one used in the single-speed DX coil. The number of speed levels can range from 1 to 10. The cooling coil has two indoor air side connections, and one optional condenser air node connection. The user needs to specify a nominal speed level, at which the rated total cooling capacity, and rated volumetric air rate are sized. The rated capacity and rated volumetric flow rate represent the real situation in the

air loop, and are used to determine air flow rates at various speed levels in the parent objects, e.g. of AirLoopHVAC:UnitaryHeatCool, ZoneHVAC:PackagedTerminalAirConditioner, AirLoopHVAC:UnitaryHeatPump:AirToAir and ZoneHVAC:PackagedTerminalHeatPump. It shall be mentioned that the performance correction curves, i.e. the temperature and flow fraction correction curves, should be normalized to the capacity and flow rate at each individual speed and at the rated conditions, similar to the performance curves used in the single-speed DX coil. However, the performance values, e.g. capacities, COPs, SHRs and flow rates at individual speed levels, should be given regarding a specific unit from the Reference Unit catalog data. In the following content, the statement started with "Reference Unit" means the actual Reference Unit catalog data. The rated conditions for obtaining the capacities, COPs and SHRs are at indoor dry-bulb temperature of 26.67 °C (80 °F), wet bulb temperature of 19.44 °C (67 °F), and the condenser entering air temperature of 35 °C (95 °F). Some equations are provided below to help explain the function of the various performance curves and data fields.

Field: Name

This alpha field contains the identifying name for the variable-speed cooling coil.

Field: Air Inlet Node Name

This alpha field contains the cooling coil load side inlet node name.

Field: Air Outlet Node Name

This alpha field contains the cooling coil load side outlet node name.

Field: Number of Speeds

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, should be equal or higher than the maximum number. The performance inputs at higher speed levels are ignored.

Field: Nominal Speed Level

This numeric field defines the nominal speed level, at which the rated capacity and rated air rate are correlated.

Field: Rated Total Cooling Capacity at Selected Nominal Speed Level

This numeric field contains the rated total cooling capacity at the nominal speed level. This field is autosizable. The rated total cooling capacity is used to determine a capacity scaling factor, as compared to the Reference Unit capacity at the nominal speed level.

$$\text{CapacityScaleFactor} = \frac{\text{Rated Total Cooling Capacity}}{\text{Reference Unit Capacity @ Nominal Speed Level}}$$

And then, this scaling factor is used to determine capacities at rated conditions for other speed levels, as below,

$$\begin{aligned} \text{Rated Capacity @ Speed Level}(x) &= \\ &\text{CapacityScaleFactor} \times \\ &\text{Reference Unit Capacity @ Speed Level}(x) \end{aligned}$$

Field: Rated Volumetric Air Flow Rate at Selected Nominal Speed Level

This numeric field contains the rated volumetric air flow rate on the load side of the DX unit, corresponding to the nominal speed level. This field is autosizable. The value is used to

determine an internal scaling factor, and calculate the air flow rates in the parent objects. It is recommended that the ratio of the rated volumetric air flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\text{AirFlowScaleFactor} = \frac{\text{Rated Volumetric Air Flow Rate}}{\text{Reference Unit Vol Air Flow Rate @ Nominal Speed Level} \times \text{CapacityScaleFactor}}$$

And the volumetric air flow rates in the parent objects are calculated as below,

$$\begin{aligned} \text{Loop Volumetric Air Flow Rate @ Speed Level}(x) &= \\ &\text{AirFlowScaleFactor} \times \\ &\text{Reference Unit Vol Air Flow Rate @ Speed Level}(x) \times \\ &\text{CapacityScaleFactor} \end{aligned}$$

Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the unit as a function of the part load ratio (PLR, sensible or latent load/steady-state sensible or latent cooling capacity for Speed 1), in the case that the unit operates under the lowest speed, i.e. on/off. The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep for Speed 1. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep).

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are AirCooled or EvaporativelyCooled. The default for this field is AirCooled.

Field: Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = Air Cooled.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air drybulb temperature is below the value specified in the input field "Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation" (described below), the crankcase heater is enabled during the time that the compressor is not running. If this cooling coil is used as part of an air-to-air heat pump, the crankcase heater defined for this DX cooling coil is ignored and the crankcase heater power defined for the DX heating coil (Ref. Coil:Heating:DX:SingleSpeed) is enabled during the time that the compressor is not running for either heating or cooling. The value for this input field must be greater than or equal to 0, and the default value is 0. To simulate a DX cooling coil without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C, and the default value is 10°C.

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the coil obtains water used for evaporative cooling of its condenser. If blank or omitted, then the unit will obtain water directly from the mains. If the name of a Water Storage Tank object is used here, the unit will obtain its water from that tank. If a tank is specified, the unit will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the condenser needs, then the unit will still operate and obtain the rest of the water it needs from the mains (referred to as StarvedWater).

Field: Condensate Collection Water Storage Tank Name

This field is optional. It is used to describe where condensate from the coil is collected. If blank or omitted, then any coil condensate is discarded. Enter the name of Water Storage Tank object defined elsewhere and the condensate will then be collected in that tank.

Field: Basin Heater Capacity

This numeric field contains the capacity of the DX coil's electric evaporative cooler basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the DX coil is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The

basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the DX coil is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the DX coil is off.

Field Group: Rated specification, performance curves

The performance for each cooling speed must be specified as shown below. They should be directly given from the Reference Unit catalog data. All inputs for Speed 1 are required, followed by the optional inputs for other speeds.

Field: Speed <x> Reference Unit Total Cooling Capacity

This numeric field defines the total, full load cooling capacity in watts of the air-to-air cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. Capacity should not include supply air fan heat.

Field: Speed <x> Reference Unit SHR

This numeric field defines sensible heat transfer ratio (SHR = sensible heat transfer rate divided by total cooling capacity) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0.0 and less than 1.0. This value should be obtained from the Reference Unit data.

Field: Speed <x> Reference Unit COP

This numeric field defines the coefficient of performance (COP=total cooling capacity output in watts divided by electrical power input in watts) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The input power includes power for the compressor(s) and accessories, but does not include the indoor supply air fan.

Field: Speed <x> Reference Unit Air Flow Rate

This numeric field defines the volumetric air flow rate, in m³ per second, across the cooling coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given cooling capacity and COP at the speed, as above.

Field: Speed <x> Reference Unit Condenser Flow Rate

This numeric field defines the condenser volumetric air flow rate, in m³ per second, across the condenser coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data. This field is used to calculate water evaporation rate for an evaporatively-cooled condenser. For an air-cooled condenser, this input is not used.

Field: Speed <x> Reference Unit Pad Effectiveness of Evap Precooling

This numeric field defines the effectiveness of condenser evaporative precooling pad. The values of effectiveness are given at individual speed levels, since varied condenser air flow rates impact the effectiveness.

Field: Speed <x> Total Cooling Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the both the indoor wet-bulb and source side entering air temperature, from the Reference Unit. The output of this curve is multiplied by the rated total cooling capacity at the speed to give the total cooling capacity at specific temperature operating conditions (i.e., at an indoor air wet-bulb temperature or outdoor entering air temperature different from the rating point temperature). It should be noted that the curve is normalized to the cooling capacity at Speed<x> from the Reference Unit data, and have the value of 1.0 at the rating point.

Field: Speed <x> Total Cooling Capacity Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow at Speed <x>, from the Reference Unit data). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the design air flow rate, at Speed <x>.

Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor air wet-bulb and condenser entering air temperatures. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP at Speed <x> from the Reference Unit data) to give the EIR at specific temperature operating conditions (i.e., at an indoor air wet-bulb temperature or condenser entering air temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Energy Input Ratio Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). The EIR is the inverse of the COP. This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

An example of this statement in an IDF is:

VSAirtoAirHP Power [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

VSAirtoAirHP Load Side Total Heat Transfer Rate [W]

The output variable is the average total cooling load provide by the heat pump which includes the sensible and latent load in Watts over the timestep being reported.

VSAirtoAirHP Load Side Sensible Heat Transfer Rate [W]

The output variable is the average sensible cooling load provide by the heat pump in Watts over the timestep being reported.

VSAirtoAirHP Source Side Total Heat Transfer Rate [W]

The output variable is the average heat rejected to the water at the heat pump condenser in Watts over the timestep being reported.

VSAirtoAirHP Part-Load Ratio

This output variable is the ratio of the part-load capacity to the steady state capacity of the VSAirtoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the VSAirtoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

VSAirtoAirHP Duty Factor

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

VSAirtoAirHP Load Side Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

VSAirtoAirHP Load Side Inlet Dry Bulb Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

VSAirtoAirHP Load Side Inlet Humidity Ratio [kg/kg]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

VSAirtoAirHP Load Side Outlet Dry Bulb Temperature [C]

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

VSAirtoAirHP Load Side Outlet Humidity Ratio [kg/kg]

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

VSAirtoAirHP Source Side Mass Flow Rate [kg/s]

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

VSAirtoAirHP Source Side Inlet Temperature [C]

The output variable is the average entering water temperature over the timestep being reported.

VSAirtoAirHP Source Side Outlet Temperature [C]

The output variable is the average leaving water temperature over the timestep being reported.

VSAirtoAirHP Upper Speed Level []

The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

VSAirtoAirHP Speed Ratio between Two Neighboring Speeds []

The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

VSAirtoAirHP Recoverable Waste Heat [W]

This output variable is the average recoverable waste heat rate of the heat pump in Watts over the timestep being reported.

VSAirtoAirHP Cooling Electric Consumption [J]

The output variable is the electric consumption of the heat pump in Joules over the timestep being reported.

VSAirtoAirHP Load Side Total Cooling Energy [J]

The output variable is the total cooling output of the coil in Joules over the timestep being reported.

VSAirtoAirHP Load Side Sensible Cooling Energy [J]

The output variable is the total sensible cooling output of the coil in Joules over the timestep being reported

VSAirtoAirHP Load Side Latent Cooling Energy [J]

The output variable is the total latent cooling output of the coil in Joules over the timestep being reported.

VSAirtoAirHP Source Side Cooling Energy [J]

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

VSAirtoAirHP Cooling Coil Crankcase Heater Power [W]

The output variable is the average power used for crankcase heater, in Watts over the timestep being reported.

VSAirtoAirHP Cooling Coil Crankcase Heater Consumption [J]

The output variable is the total electric energy usage of the coil for crankcase heater, in Joules over the timestep being reported.

VSAirtoAirHP Cooling Coil Condensate Volumetric Flow Rate [m³/s]

The output variable is the average water condensate volumetric flow rate from the cooling coil, in m³/s over the timestep being reported, if choosing to use CondensateToTank.

VSAirtoAirHP Cooling Coil Condensate Volume [m³]

The output variable is the total water condensate volume from the cooling coil, in m³ over the timestep being reported.

VSAirtoAirHP Cooling Coil Condenser Inlet Temp [C]

The output variable is the average air temperature entering the condenser coil, in °C over the timestep being reported.

VSAirtoAirHP Cooling Coil Evap Condenser Water Consumption [m³]

The output variable is the total water volume consumed for condenser evaporative pre-cooling, in m³ over the timestep being reported.

Mains Water Supply for VSAirtoAirHP Cooling Coil Evap Condenser [m³]

The output variable is the total water volume for condenser evaporative pre-cooling, obtained from the Mains Water supply, in m³ over the timestep being reported.

VSAirtoAirHP Cooling Coil Evap Condenser Pump Electric Power[W]

The output variable is the average power consumption rate of the evaporative condenser pump, in Watts over the timestep being reported.

VSAirtoAirHP Cooling Coil Evap Condenser Pump Electric Consumption[J]

The output variable is the total power consumption of the evaporative condenser pump, in Joules over the timestep being reported.

VSAirtoAirHP Cooling Coil Basin Heater Electric Power [W]

The output variable is the average power consumption rate by the basin heater, in Watts over the timestep being reported.

VSAirtoAirHP Cooling Coil Basin Heater Electric Consumption [J]

The output variable is the total power consumption by the basin heater, in Joules over the timestep being reported.

CoilPerformance:DX:Cooling

This coil performance object is used to specify DX coil performance for one mode of operation for a Coil:Cooling:DX:TwoStageWithHumidityControlMode. A single Coil:Cooling:DX:TwoStageWithHumidityControlMode object will reference one to four CoilPerformance:DX:Cooling objects depending on the number of available stages and dehumidification modes as specified in the two stage DX object. For example, a standard 2-

stage DX system will use two of these performance objects, one to defined the capacity and performance for stage 1 operation, and a second one for stage 1+2 (both stages active) operation. In nearly all cases, the Rated Air Volume Flow Rate will be the same for all performance objects associated with a given multimode DX coil. If bypass is specified, the Rated Air Volume Flow Rate includes both the bypassed flow and the flow through the active coil.

This DX coil model is identical to Coil:Cooling:DX:SingleSpeed with addition of bypass and multi-stage capabilities. This DX cooling coil model and input are quite different from that for the heating and cooling water coils. The simple water coils use an NTU-effectiveness heat exchanger model. The single speed DX coil model uses performance information at rated conditions along with curve fits for variations in total capacity, energy input ratio and part-load fraction to determine performance at part-load conditions. Sensible/latent capacity splits are determined by the rated sensible heat ratio (SHR) and the apparatus dewpoint/bypass factor (ADP/BF) approach. This approach is analogous to the NTU-effectiveness calculations used for sensible-only heat exchanger calculations, extended to a cooling and dehumidifying coil.

The DX cooling coil input requires the rated total cooling capacity, the rated SHR, the rated COP, the rated air volume flow rate, and the fraction of air flow which is bypassed around the coil. The first 4 inputs determine the coil performance at the rating point (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb and air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb). The rated air volume flow rate (less any bypassed fraction) should be between .00004027 m³/s and .00006041 m³/s per watt of rated total cooling capacity (300 to 450 cfm/ton).

This model requires 5 curves as follows:

1. The total cooling capacity modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
2. The total cooling capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating.
3. The energy input ratio (EIR) modifier curve (function of temperature) is a biquadratic curve with two independent variables: wet-bulb temperature of the air entering the cooling coil, and dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures).
4. The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
5. The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible cooling load / steady-state sensible cooling capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor

cycling. The curve should be normalized to a value of 1.0 when the part-load ratio equals 1.0 (i.e., the compressor(s) run continuously for the simulation timestep).

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (see Performance Curves in this document).

The next four input fields are optional and relate to the degradation of latent cooling capacity when the supply air fan operates continuously while the cooling coil/compressor cycle on and off to meet the cooling load. The fan operating mode is either considered to be constant (e.g. CoilSystem:Cooling:DX) or can be scheduled in the parent object (e.g. AirLoopHVAC:UnitaryHeatCool). When scheduled, the schedule value must be greater than 0 to calculate degradation of latent cooling capacity. At times when the parent object's supply air fan operating mode schedule is 0, latent degradation will be ignored. When used, these next four input fields must all have positive values in order to model latent capacity degradation.

The next input specifies the outdoor air node used to define the conditions of the air entering the outdoor condenser. If this field is not blank, the node name specified must be listed in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor temperature from the weather data. Alternately, the node name must be specified in an OutdoorAir:NodeList object where the outdoor temperature entering the condenser is taken directly from the weather data. This field may also be left blank, if this is the case then the outdoor temperature entering the condenser is taken directly from the weather data.

The next input describes the type of outdoor condenser coil used with the DX cooling coil (Air Cooled or Evap Cooled). The following three inputs are required when modeling an evaporative-cooled condenser: evaporative condenser effectiveness, evaporative condenser air volume flow rate, and the power consumed by the evaporative condenser pump. See section “DX Cooling Coil Model” in the EnergyPlus Engineering Document for further details regarding this model.

Field: Name

This alpha field is a unique user-assigned name for an instance of DX cooling coil performance. Any reference to this DX coil performance object by another object will use this name.

Field: Rated Total Cooling Capacity

The total, full load cooling capacity (sensible plus latent) in watts of the DX coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb¹², and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Capacity should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated Sensible Heat Ratio

The sensible heat ratio (SHR=sensible capacity divided by total cooling capacity) of the DX cooling coil at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow rate” below). Both the sensible and total cooling capacities used to define the Rated SHR should be “gross” (i.e., supply air fan heat is NOT included).

Field: Rated COP

The coefficient of performance (COP=cooling power output in watts divided by electrical power input in watts) of the DX cooling coil unit at rated conditions (air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/ 23.9°C wetbulb, and a cooling coil air flow rate defined by field “rated air volume flow

¹² The 23.9°C wet-bulb temperature condition is not applicable for air-cooled condensers which do not evaporate condensate.

rate" below). The input power includes electric power for the compressor(s) and condenser fan(s) but does not include the power consumption of the supply air fan. The cooling power output is the value entered above in the field "Rated Total Cooling Capacity (gross)". If this input field is left blank, the default value is 3.0.

Field: Rated Air Flow Rate

The air volume flow rate, in m^3 per second, across the DX cooling coil at rated conditions. The rated total cooling capacity, rated SHR and rated COP should be performance information for the unit with air entering the cooling coil at 26.7°C drybulb/19.4°C wetbulb, air entering the outdoor condenser coil at 35°C drybulb/23.9°C wetbulb, and the rated air volume flow rate defined here.

Field: Fraction of Air Flow Bypassed Around Coil

This numeric field specifies the fraction of the Rated Air Volume Flow Rate which bypasses the active cooling coil for this performance mode. The remaining portion of the flow should be between 0.00004027 m^3/s and .00006041 m^3/s per watt of rated total cooling capacity (300 to 450 cfm/ton) for this performance mode. This is used to model face-split coils on multi-stage units or bypass dampers. If total flow rate varies during simulation, the same fraction is bypassed. This input may range from 0.0 to <1.0. The default is 0.0. For a multi-stage face-split coil in which stage 1 is 60% of total capacity, this field would be set to 0.4 for the Stage 1 performance and set to 0.0 for the Stage 1+2 performance. For a DX system which activates a bypass damper for improved dehumidification, this field would be set to 0.0 for normal mode performance and set to something greater than zero for enhanced dehumidification mode performance.

Field: Total Cooling Capacity Function of Temperature Curve Name

The name of a **biquadratic** performance curve (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The output of this curve is multiplied by the rated total cooling capacity to give the total cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to have the value of 1.0 at the rating point.

Field: Total Cooling Capacity Function of Flow Fraction Curve Name

The name of a **quadratic** or **cubic** performance curve (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total cooling capacity and the total cooling capacity modifier curve (function of temperature) to give the total cooling capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Energy Input Ratio Function of Temperature Curve Name

The name of a **biquadratic** performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the wet-bulb temperature of the air entering the cooling coil, and the dry-bulb temperature of the air entering the air-cooled condenser coil (wet-bulb temperature if modeling an evaporative-cooled condenser). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the rating point temperatures). The curve is normalized to a value of 1.0 at the rating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

The name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the cooling coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Nominal Time for Condensate Removal to Begin

The nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other “parent” objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]), and this field as well as the next three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

Ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other “parent” objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]); and this field, the previous field and the next two fields must have positive values in order to model latent capacity degradation.

Field: Maximum Cycling Rate

The maximum on-off cycling rate for the compressor (cycles per hour), which occurs at 50% run time fraction. Suggested value is 3; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other "parent" objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]); and this field, the previous two fields and the next field must have positive values in order to model latent capacity degradation.

Field: Latent Capacity Time Constant

Time constant (in seconds) for the cooling coil's latent capacity to reach steady state after startup. Suggested value is 45; zero value means latent degradation model is disabled. The default value for this field is zero. The supply air fan operating mode must be continuous (i.e., the supply air fan operating mode may be specified in other "parent" objects and is assumed continuous in some objects (e.g., CoilSystem:Cooling:DX) or can be scheduled in other objects [e.g., AirloopHVAC:UnitaryHeatCool]), and this field as well as the previous three input fields for this object must have positive values in order to model latent capacity degradation.

Field: Condenser Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor condenser. If this field is left blank, the outdoor air temperature entering the condenser (dry-bulb or wet-bulb) is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Field: Condenser Type

The type of condenser used by the DX cooling coil. Valid choices for this input field are **AirCooled** or **EvaporativelyCooled**. The default for this field is **AirCooled**.

Field: Evaporative Condenser Effectiveness

The effectiveness of the evaporative condenser, which is used to determine the temperature of the air entering the outdoor condenser coil as follows:

$$T_{cond\ inlet} = (T_{wb,o}) + (1 - EvapCondEffectiveness)(T_{db,o} - T_{wb,o})$$

where

$T_{cond\ inlet}$ = the temperature of the air entering the condenser coil (C)

$T_{wb,o}$ = the wet-bulb temperature of the outdoor air (C)

$T_{db,o}$ = the dry-bulb temperature of the outdoor air (C)

The resulting condenser inlet air temperature is used by the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature). The default value for this field is 0.9, although valid entries can range from 0.0 to 1.0. This field is not used when Condenser Type = Air Cooled.

If the user wants to model an air-cooled condenser, they should simply specify AirCooled in the field Condenser Type. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields

for this object should reference performance curves that are a function of outdoor dry-bulb temperature.

If the user wishes to model an evaporative-cooled condenser AND they have performance curves that are a function of the wet-bulb temperature of air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled and the evaporative condenser effectiveness value should be entered as 1.0. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of the wet-bulb temperature of air entering the condenser coil.

If the user wishes to model an air-cooled condenser that has evaporative media placed in front of it to cool the air entering the condenser coil, then the user should specify Condenser Type = Evap Cooled. The user must also enter the appropriate evaporative effectiveness for the media. In this case, the Total Cooling Capacity Modifier Curve (function of temperature) and the Energy Input Ratio Modifier Curve (function of temperature) input fields for this object should reference performance curves that are a function of outdoor dry-bulb temperature. Be aware that the evaporative media will significantly reduce the dry-bulb temperature of the air entering the condenser coil, so the Total Cooling Capacity and EIR Modifier Curves must be valid for the expected range of dry-bulb temperatures that will be entering the condenser coil.

Field: Evaporative Condenser Air Flow Rate

The air volume flow rate, in m^3 per second, entering the evaporative condenser. This value is used to calculate the amount of water used to evaporatively cool the condenser inlet air. The minimum value for this field must be greater than zero, and this input field is autosizable (equivalent to 0.000144 m^3/s per watt of rated total cooling capacity [850 cfm/ton]). This field is not used when Condenser Type = Air Cooled.

Field: Evaporative Condenser Pump Rated Power Consumption

The rated power of the evaporative condenser water pump in Watts. This value is used to calculate the power required to pump the water used to evaporatively cool the condenser inlet air. The default value for this input field is zero, but it is autosizable (equivalent to 0.004266 W per watt [15 W/ton] of rated total cooling capacity). This field is not used when Condenser Type = AirCooled.

Following is an example input for a Coil:Cooling:DX:TwoStageWithHumidityControlMode with 2 capacity stages and one enhanced dehumidification mode so it requires four CoilPerformance:DX:Cooling objects.

Coil Performance DX Cooling Outputs

The CoilPerformance:DX:Cooling object does not have specific output variables. To request reports, use the parent object Coil:Cooling:DX:TwoStageWithHumidityControlMode output variable options (ref. DX Cooling Coil Outputs). When requesting specific output variables by name, use the name of the parent object as the Key Value for Output:Variable reporting objects (ref. Output:Variable). The name of the CoilPerformance:DX:Cooling object cannot be used as a Key Value in the Output:Variable object.

Coil:Heating:DX:SingleSpeed

The single speed heating DX coil model uses performance information at rated conditions along with curve fits for variations in total capacity, energy input ratio and part load fraction to determine performance at part-load conditions. The impacts of various defrost strategies (reverse cycle, resistive, timed or on-demand) are modeled based on a combination of user inputs and empirical models taken from the air-to-air heat pump algorithms in DOE-2.1E.

The single speed heating DX coil input requires an availability schedule, the rated total heating capacity, the rated COP and the rated air volume flow rate. The latter 3 inputs determine the coil performance at the rating point (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, coil entering air dry-bulb temperature of 21.11 C, coil entering air wet-bulb temperature of 15.55 C). The rated air volume flow rate should be between .00004027 m³/s and .00006041 m³/s per watt of rated total heating capacity.

Up to 6 curves are required depending on the defrost strategy selected.

- 1) The total heating capacity modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 2) The total heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating.
- 3) The energy input ratio (EIR) modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor

air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).

- 4) The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
- 5) The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible heating load / steady-state heating capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction correlation accounts for efficiency losses due to compressor cycling.
- 6) The defrost energy input ratio (EIR) modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: outdoor air dry-bulb temperature and the heating coil entering air wet-bulb temperature. The output of this curve is multiplied by the heating coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the coil is operating. This curve is only required when a reverse-cycle defrost strategy is specified.

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (ref. Performance Curves).

The next input item for the coil is the supply air fan operation mode. Either the supply air fan runs continuously while the DX coil cycles on/off, or the fan and coil cycle on/off together. The next two inputs define the minimum outdoor dry-bulb temperature that the heat pump compressor will operate and the maximum outdoor dry-bulb temperature for defrost operation. Crankcase heater capacity and cutout temperature are entered in the following two inputs. The final four inputs cover the type of defrost strategy (reverse-cycle or resistive), defrost control (timed or on-demand), the fractional defrost time period (timed defrost control only), and the resistive defrost heater capacity if a resistive defrost strategy is selected.

Field: Name

This alpha field defines a unique user-assigned name for an instance of a DX heating coil. Any reference to this DX heating coil by another object will use this name.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the DX heating coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Rated Total Heating Capacity

This numeric field defines the total, full load heating capacity in watts of the DX coil unit at rated conditions (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field “rated air flow volume” below). The value entered here must be greater than 0. Capacity

should not include supply air fan heat. The rated total heating capacity should be within 20% of the rated total cooling capacity, otherwise a warning message is issued.

Field: Rated COP

This numeric field defines the coefficient of performance (COP=heating power output in watts divided by electrical power input in watts) of the DX heating coil unit at rated conditions (outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, coil entering air dry-bulb temperature of 21.11 C, coil entering air wet-bulb temperature of 15.55 C, and a heating coil air flow rate defined by field "rated air flow volume rate" below). The value entered here must be greater than 0. The input power includes power for the compressor(s) and outdoor fan(s) but does not include the power consumption of the indoor supply air fan. The heating power output is the value entered above in the field "Rated Total Heating Capacity".

Field: Rated Air Flow Rate

This numeric field defines the volume air flow rate, in m^3 per second, across the DX heating coil at rated conditions. The value entered here must be greater than 0. The rated air volume flow rate should be between 0.00004027 m^3/s and 0.00006041 m^3/s per watt of rated total heating capacity. The rated total heating capacity and rated COP should be performance information for the unit with outdoor air dry-bulb temperature of 8.33 C, outdoor air wet-bulb temperature of 6.11 C, heating coil entering air dry-bulb temperature of 21.11 C, heating coil entering air wet-bulb temperature of 15.55 C, and the rated air volume flow rate defined here.

Field: Rated Evaporator Fan Power Per Volume Flow Rate

This field is the electric power for the evaporator (heating coil) fan per air volume flow rate through the coil at the rated conditions in $W/(m^3/s)$. The default value is 773.3 $W/(m^3/s)$ (365 $W/1000 \text{ cfm}$) if this field is left blank. If a value is entered, it must be ≥ 0.0 and $\leq 1250 W/(m^3/s)$. This value is only used to calculate High Temperature Heating Standard (Net) Rating Capacity, Low Temperature Heating Standard (Net) Rating Capacity and Heating Seasonal Performance Factor (HSPF) which will be outputs in the EnergyPlus eio file (ref. EnergyPlus Engineering Reference, Single Speed DX Heating Coil, Standard Ratings). This value is not used for modeling the evaporator (heating coil) fan during simulations; instead, it is used for calculating the above standard ratings to assist the user in verifying their inputs for modeling this type of equipment.

Field: Air Inlet Node Name

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

Field: Total Heating Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Total Heating Capacity Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Energy Input Ratio Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Defrost Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the outdoor air dry-bulb temperature and the wet-bulb temperature of the air entering the indoor coil. The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse-cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the heating coil compressor turns off. The temperature for this input field must be greater than or equal to -20 C. If this input field is left blank, the default value is -8 C.

Field: Outdoor Dry-Bulb Temperature to Turn On Compressor

This numeric field defines the outdoor air dry-bulb temperature when the compressor is automatically turned back on following an automatic shut off because of low outdoor temperature. This field is only used for the calculation heating seasonal performance factor (HSPF) of heating coil. If this field is not provided, outdoor bin temperature is always considered to be greater than this temperature and 'Minimum Outdoor dry-bulb Temperature for Compressor Operation' field described above.

Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 C and less than or equal to 7.22 C. If this input field is left blank, the default value is 5 C.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field "Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation" (described below), the crankcase heater is enabled during the time that the compressor is not running. If this heating coil is used as part of an air-to-air heat pump (Ref. AirLoopHVAC:UnitaryHeatPump:AirToAir or ZoneHVAC:PackagedTerminalHeatPump), the crankcase heater defined for this DX heating coil is enabled during the time that the compressor is not running for either heating or cooling (and the crankcase heater power defined in the DX cooling coil object is disregarded in this case). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 C. If this input field is left blank, the default value is 10 C.

Field: Defrost Strategy

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle.

Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

Field: Region Number

This optional numeric field defines the region number which is used to calculate HSPF of heating coil. The value for this input field must be between 1 and 6. If this input field is left blank, the default value is 4.

Field: Evaporator Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the outdoor evaporator. If this field is left blank, the outdoor air temperature entering the evaporator is taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data.

Following is an example input for the object.

DX Coil Total Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Heating Energy[J]

This is the total heating output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (ref. Report Meter).

DX Heating Coil Electric Power[W]

This output is the electricity consumption rate of the DX coil compressor and outdoor fan(s) in Watts. This rate is applicable when the unit is providing heating to the conditioned zone(s), and excludes periods when the unit is in reverse-cycle defrost mode.

DX Heating Coil Electric Consumption[J]

This is the electricity consumption of the DX coil compressor and condenser fan(s) in Joules for the timestep being reported. This consumption is applicable when the unit is providing heating to the conditioned zone(s), and excludes periods when the unit is in reverse-cycle defrost mode. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

DX Heating Coil Electric Defrost Power[W]

This is the electricity consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle or resistive).

DX Heating Coil Electric Defrost Consumption[J]

This is the electricity consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive).

DX Heating Coil Crankcase Heater Power[W]

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported.

DX Heating Coil Crankcase Heater Consumption[J]

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Miscellaneous, Group Key = System (ref. Report Meter).

DX Heating Coil Runtime Fraction

This is the runtime fraction of the DX heating coil compressor and outdoor fan(s) for the timestep being reported.

Coil:Heating:DX:MultiSpeed

This component models a DX heating unit with multiple discrete levels of heating capacity. Currently, this heating coil can only be referenced by a AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed compound object. The multispeed DX heating coil can have from two to four operating speeds. When the coil operates at Speed 1 (the lowest speed), its performance is very similar to the Coil:Heating:DX:SingleSpeed object where the impacts of part-load ratio can be included. When the coil operates at higher speeds (above Speed 1), the linear approximation methodology is applied. The coil outputs at two consecutive speeds are linearly interpolated to meet the required heating capacity during an HVAC system timestep. When the coil performs above the lowest speed, the user can choose if they want to include part-load ratio impacts at the higher speeds.

The multispeed unit is described by specifying the performance at different operating speeds. Each speed has its own set of input specifications: full load capacity, COP and air flow rate at rated conditions, along with modifier curves to determine performance when actual operating conditions are different from the rated conditions.

The coil operates to meet the sensible capacity being requested. When this requested capacity is above the sensible capacity of the highest operating speed, the coil runs continuously at the highest speed. When the requested capacity is between the sensible capacities of two consecutive speeds, the unit will operate a portion of the time at each speed to meet the request. When the requested capacity is less than the low speed (Speed 1) capacity, the unit will cycle on/off as needed.

The next input defines the minimum outdoor dry-bulb temperature where the compressor will operate. The followed two inputs are related to crankcase heater operation: capacity and maximum outdoor dry-bulb temperature for crankcase heater operation. The next six inputs cover defrost operation: defrost EIR modifier curve, the maximum outdoor dry-bulb temperature for defrost operation, the type of defrost strategy (reverse-cycle or resistive), defrost control (timed or on-demand), the fractional defrost time period (timed defrost control only), and the resistive defrost heater capacity if a resistive defrost strategy is selected. The activation of defrost is dependent on outdoor conditions. The capacity reduction and energy use modification are independent of speed. The defrost EIR modifier is described below:

The defrost energy input ratio (EIR) modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: outdoor air dry-bulb temperature and the heating coil entering air wet-bulb temperature. The output of this curve is multiplied by the heating coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the coil is operating. This curve is only required when a reverse-cycle defrost strategy is specified.

The next input allows the user to choose whether to apply the part load fraction correlation to speeds greater than 1 or not. The following input is the type of fuel.

Then the number of speed for heating is entered. The rest of inputs are speed dependent. Each set of data consists of rated heating capacity, rated COP, and the rated air volume flow rate. These three inputs determine the coil performance at the rating point (outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, coil entering air dry-bulb temperature of 21.11°C, coil entering air wet-bulb temperature of 15.55°C). The rated air volume flow rate should be between .00004027 m³/s and .00006041 m³/s per watt of rated

total heating capacity. The rated waste heat fraction is needed to calculate how much waste heat is available at the rated conditions. In addition, up to 6 modifier curves are required per speed.

- 1) The total heating capacity modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 2) The total heating capacity modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating.
- 3) The energy input ratio (EIR) modifier curve (function of temperature) can be a function of both the outdoor and indoor air dry-bulb temperature or only the outdoor air dry-bulb temperature. User has the choice of a bi-quadratic curve with two independent variables or a quadratic curve as well as a cubic curve with a single independent variable. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated EIR (inverse of the rated COP) to give the EIR at specific temperature operating conditions (i.e., at an outdoor or indoor air temperature different from the rating point temperature).
- 4) The energy input ratio (EIR) modifier curve (function of flow fraction) is a quadratic or cubic curve with the independent variable being the ratio of the actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated EIR (inverse of the rated COP) and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating.
- 5) The part load fraction correlation (function of part load ratio) is a quadratic or cubic curve with the independent variable being part load ratio (sensible heating load / steady-state heating capacity). The output of this curve is used in combination with the rated EIR and EIR modifier curves to give the “effective” EIR for a given simulation timestep. The part load fraction correlation accounts for efficiency losses due to compressor cycling.
- 6) The waste heat modifier curve (function of temperature) is a bi-quadratic curve with two independent variables: outdoor air dry-bulb temperature and the heating coil entering air dry-bulb temperature. The output of this curve is multiplied by the heating input energy, the waste heat fraction of heat input to give the recoverable waste heat.

The curves are simply specified by name. Curve inputs are described in the curve manager section of this document (ref. Performance Curves).

Field: Name

This alpha field defines a unique user-assigned name for an instance of a multispeed DX heating coil. Any reference to this DX heating coil by another object will use this name. The only allowed parent is AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed.

Field: Availability Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the multispeed DX heating coil can run during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the unit can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the unit must be off for the hour.

Field: Air Inlet Node name

This alpha field defines the name of the HVAC system node from which the DX heating coil draws its inlet air.

Field: Air Outlet Node Name

This alpha field defines the name of the HVAC system node to which the DX heating coil sends its outlet air.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the heating coil compressor turns off. The temperature for this input field must be greater than or equal to -20°C. If this input field is left blank, the default value is -8°C.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air dry-bulb temperature is below the value specified in the input field "Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation" (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0°C. If this input field is left blank, the default value is 10°C.

Field: Defrost Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the outdoor air dry-bulb temperature and the wet-bulb temperature of the air entering the indoor coil. The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse-cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0°C and less than or equal to 7.22°C. If this input field is left blank, the default value is 5°C.

Field: Defrost Strategy

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse-cycle.

Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field “Defrost Time Period Fraction” described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

Field: Apply Part Load Fraction to Speeds Greater than 1

This field determines whether part-load impacts on coil energy use are applied when the coil is operating at speeds greater than speed 1. The allowed choices are Yes or No, with the default being No if this field is left blank. Other input fields in this object allow the user to specify a part-load fraction correlation for each speed to account for compressor start up losses (cycle on/off). For the case of a single multi-speed compressor, the part load losses may only be significant when the compressor cycles between speed 1 and off, but the losses may be extremely small when the compressor operates between speed 1 and speed 2 (or between speeds 2 and 3, etc.). In this case, the user may chose to specify **No** for this input field to neglect part-load impacts on energy use at higher operating speeds. If part-load impacts on coil energy use are thought to be significant (e.g., intertwined cooling coil with multiple compressors feeding individual refrigerant circuits), then the user may chose to specify **Yes** and the part-load fraction correlations specified for speeds 2 through 4 will be applied as appropriate. The selection for this input field does not affect part-load impacts when the compressor cycles between speed 1 and off (i.e., the part-load fraction correlation for speed 1 is always applied).

Field: Fuel Type

This alpha field determines the type of fuel that the chiller uses. This field has seven choices: Electricity, NaturalGas, PropaneGas, Diesel, Gasoline, FuelOil#1, and FuelOil#2. The default is NaturalGas.

Field: Number of Speeds

This field specifies the number of sets of data being entered for rated specifications, performance curves, and waste heat specifications for each cooling speed. The rated specifications consist of rated capacity, rated COP, and rated air flow rate. The performance curves consist of a total capacity modifier curve as a function of temperature, total capacity modifier curve as a function of flow fraction, energy input ratio modifier curve as a function of temperature, energy input ratio modifier curve as a function of flow fraction, and part load fraction correlation as a function of part load ratio. The waste heat specifications include the fraction of energy input to the heating coil at the fully loaded and rated conditions, and a

temperature modifier. The minimum number of speeds for heating is 2 and the maximum number is 4. The number of speeds should be the same as the number of speeds for heating defined in its parent object (AirLoopHVAC:UnitaryHeatPump:AirToAir:MultiSpeed). The first set of performance inputs is for Speed 1 and should be for low speed, and the last set of performance inputs should be for high speed. For example, if only three heating speeds are defined, the first set should be for low speed (Speed 1), the second set should be for medium speed (Speed 2), and the third set should be for high speed (Speed 3). In this example, any performance inputs for Speed 4 would be neglected (since this input field specifies that the coil only has three heating speeds).

Field Group: rated specification, performance curves, and waste heat data

The performance for each heating speed must be specified as shown below. All inputs for Speed 1 are required first, followed by the inputs for Speed 2, Speed 3 and Speed 4.

Field: Speed <x> Rated Total Heating Capacity

This numeric field defines the total, full load heating capacity in watts of the DX coil unit at rated conditions for Speed <x> operation (outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, heating coil entering air dry-bulb temperature of 21.11°C, heating coil entering air wet-bulb temperature of 15.55°C, and a heating coil air flow rate defined by field “Rated Air Volume Flow Rate, Speed <x>” below). The value entered here must be greater than 0. Capacity should not include supply air fan heat.

Field: Speed <x> Rated COP

This numeric field defines the coefficient of performance (COP=heating power output in watts divided by electrical power input in watts) of the DX heating coil unit at rated conditions for Speed <x> operation (outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, coil entering air dry-bulb temperature of 21.11°C, coil entering air wet-bulb temperature of 15.55°C, and a heating coil air flow rate defined by field “Speed <x> Rated Air Flow Rate” below). The value entered here must be greater than 0. The input power includes power for the compressor(s) and outdoor fan(s) but does not include the power consumption of the indoor supply air fan. The heating power output is the value entered above in the field “Rated Total Heating Capacity”.

Field: Speed <x> Rated Air Flow Rate

This numeric field defines the volume air flow rate, in m^3 per second, across the DX heating coil at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The rated air volume flow rate should be between 0.00004027 m^3/s and 0.00006041 m^3/s per watt of rated total heating capacity. The rated total heating capacity and rated COP should be performance information for the unit with outdoor air dry-bulb temperature of 8.33°C, outdoor air wet-bulb temperature of 6.11°C, heating coil entering air dry-bulb temperature of 21.11°C, heating coil entering air wet-bulb temperature of 15.55°C, and the rated air volume flow rate defined here.

Field: Speed <x> Total Heating Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The output of this curve is multiplied by the rated total heating capacity to give the total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Total Heating Capacity Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The output of this curve is multiplied by the rated total heating capacity and the total heating capacity modifier curve (function of temperature) to give the total heating capacity at the specific temperature and air flow conditions at which the coil is operating. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor and outdoor air dry-bulb temperature or just the outdoor air dry-bulb temperature depending on the type of curve selected. The bi-quadratic curve is recommended if sufficient manufacturer data is available as it provides sensitivity to the indoor air dry-bulb temperature and a more realistic output. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or outdoor air dry-bulb temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Energy Input Ratio Function of Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the rated air flow rate (i.e., fraction of full load flow). The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR and the EIR modifier curve (function of temperature) to give the EIR at the specific temperature and air flow conditions at which the coil is operating. This curve is normalized to a value of 1.0 when the actual air flow rate equals the rated air flow rate.

Field: Speed <x> Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$ a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional DX heating coil (Speed <x>) would be:

$$PLF = 0.85 + 0.15(PLR)$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 1.0 + 0.0(PLR)$$

Field: Speed <x> Rated Waste Heat Fraction of Power Input

The fraction of heat input to heating that is available as recoverable waste heat at full load and rated conditions for Speed <x> operation.

Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of outdoor dry-bulb temperature and the entering coil dry-bulb temperature for Speed <xx>. The output of this curve is multiplied by the rated recoverable waste heat at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point. When the fuel type is electricity, the field is either left blank or ignored by the program.

Following is an example input for a multi-speed heating DX coil.

If Fuel Type is not Electricity:
HVAC,Average,DX Heating Coil <Fuel Type> Power[W]
HVAC,Sum,DX Heating Coil <Fuel Type> Consumption[J]

DX Coil Total Heating Rate [W]

This field is the total heating rate output of the DX coil in Watts. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Heating Energy [J]

This is the total heating output of the DX coil in Joules over the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil. This output is also added to a report meter with Resource Type = EnergyTransfer, End Use Key = HeatingCoil, Group Key = System (ref. Report Meter).

DX Heating Coil Electric Power [W]

This output variable is the input fuel type power for the heating coil in the unit of Watts, averaged during the report period. If Fuel Type is not Electricity, the value is zero.

DX Cooling Coil Electric Consumption [J]

This output variable is the input fuel type consumption for the multispeed heating coil in the unit of Joules, summed during the report period. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter). If Fuel Type is not Electricity, the value is zero.

DX Heating Coil Electric Defrost Power [W]

This is the electricity consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle or resistive). The variable is available when the defrost mode is resistive or the fuel type is electricity.

DX Heating Coil Electric Defrost Consumption [J]

This is the electricity consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle or resistive). The variable is available when the defrost mode is resistive or the fuel type is electricity.

DX Heating Coil <Fuel Type> Defrost Power [W]

This is the fuel consumption rate of the DX coil unit in Watts when the unit is in defrost mode (reverse-cycle). The variable is available when the defrost mode is reverse-cycle and the fuel type is non-electricity.

DX Heating Coil <Fuel Type> Defrost Consumption [J]

This is the fuel consumption of the DX coil unit in Joules for the timestep being reported. This consumption is applicable when the unit is in defrost mode (reverse-cycle). The variable is available when the defrost mode is reverse-cycle and the fuel type is non-electricity.

DX Heating Coil Crankcase Heater Power [W]

This is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. When a companion cooling coil exits, the crankcase heater power of the companion cool coil is also reported in this variable.

DX Heating Coil Crankcase Heater Consumption [J]

This is the electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Heating, Group Key = System (ref. Report Meter). When a companion cooling coil exits, the crankcase heater power of the companion cool coil is also reported in this variable.

DX Heating Coil Runtime Fraction [dimensionless]

This is the runtime fraction of the DX heating coil compressor and outdoor fan(s) for the timestep being reported. When the heating speed is above 1, this output is the run time fraction for the higher speed.

DX Heating Coil <Fuel Type> Power [W]

This output variable is the input fuel type power for the heating coil in the unit of Watts, averaged during the report period. The electric power is excluded. If Fuel Type is Electricity, this output variable is not reported.

DX Cooling Coil <Fuel Type> Consumption [J]

This output variable is the input fuel type consumption for the multispeed heating coil in the unit of Joules, summed during the report period. The electric consumption is excluded. This output is also added to a report meter with Resource Type = <Fuel Type>, End Use Key = Heating, Group Key = System (ref. Report Meter). If Fuel Type is Electricity, this output variable is not reported.

Note: The Fuel Type defined in the above two output variables depends on the input in the fuel type field. In addition to Electricity, Valid fuel types are NaturalGas, Propane, FuelOil#1, FuelOil#2, Coal, Diesel, and Gasoline.

Coil:Heating:DX:VariableSpeed

The Variable-Speed Air-to-Air Heating DX Coil is a collection of performance curves that represent the heating coil at various speed levels. The performance curves should be generated from the heat pump Reference Unit catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The number of speed levels can range from 1 to 10. The heating coil has two air side node connections. The user needs to specify a nominal speed level, at which the rated capacity and rated volumetric air flow rate are sized. The rated capacity and rated volumetric flow rate represent the real situation in the air loop, and are used to determine the flow rates at various speed levels in the parent objects, e.g. AirLoopHVAC:UnitaryHeatPump:AirToAir, ZoneHVAC:PackagedTerminalHeatPump, etc. It shall be mentioned that the performance correction curves, i.e. the temperature and flow fraction correction curves, should be normalized to the capacity and flow rate at each individual speed and at the rated operating conditions, similar to the performance curves used in the single-speed DX coil. On the other hand, the performance values at individual speed levels, e.g. capacities, COPs and flow rates, should be given regarding a specific unit from the Reference Unit catalog data. In the following content, the statement started with “Reference Unit” means the actual Reference Unit catalog data. The rated conditions for obtaining the capacities and COPs are at indoor dry-bulb temperature of 21.1 °C (70 °F) and the source side entering air temperature of 8.3 °C (47 °F). Some equations are provided below to help explain the function of the various performance curves and data fields.

Field: Name

This alpha field contains the identifying name for the variable speed heating coil.

Field: Air Inlet Node Name

This alpha field contains the heating coil load side inlet node name.

Field: Air Outlet Node Name

This alpha field contains the heating coil load side outlet node name.

Field: Number of Speeds

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, has to be equal to or higher than the maximum number. The performance inputs at higher speeds are ignored.

Field: Nominal Speed Level

This numeric field defines the nominal speed level, at which the rated capacity, rated air and volumetric flow rate are correlated.

Field: Rated Total Heating Capacity at Selected Nominal Speed Level

This numeric field contains the rated capacity at the nominal speed level. This field is autosizable. The rated heating capacity is used to determine a capacity scaling factor, as compared to the Reference Unit capacity at the nominal speed level.

$$\text{CapacityScaleFactor} = \frac{\text{Rated Total Heating Capacity}}{\text{Reference Unit Capacity @ Nominal Speed Level}}$$

And then, this scaling factor is used to determine capacities at rated conditions for other speed levels, as below,

$$\begin{aligned}\text{Rated Capacity @ Speed Level}(x) = \\ \text{CapacityScaleFactor} \times \\ \text{Reference Unit Capacity @ Speed Level}(x)\end{aligned}$$

Field: Rated Volumetric Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump corresponding to the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the air flow rates in the parent objects. It is recommended that the ratio of the rated volumetric air flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

$$\text{AirFlowScaleFactor} = \frac{\text{Rated Volumetric Air Flow Rate}}{\text{Reference Unit Vol Air Flow Rate @ Nominal Speed Level} \times \text{CapacityScaleFactor}}$$

And the volumetric air flow rates in the parent objects are calculated as below,

$$\begin{aligned}\text{Loop Volumetric Air Flow Rate @ Speed Level}(x) = \\ \text{AirFlowScaleFactor} \times \\ \text{Reference Unit Vol Air Flow Rate @ Speed Level}(x) \times \\ \text{CapacityScaleFactor}\end{aligned}$$

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the unit as a function of the part load ratio (PLR, heating load/steady-state heating capacity for Speed 1), in the case that the unit operates under the lowest speed, i.e. on/off. The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep for Speed 1. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep).

Field: Defrost Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) during reverse-cycle defrost periods as a function of the outdoor air dry-bulb temperature and the wet-bulb temperature of the air entering the indoor coil. The EIR is the inverse of the COP. The output of this curve is multiplied by the coil capacity at the maximum speed level, the fractional defrost time period and the runtime fraction of the heating coil to give the defrost power at the specific temperatures at which the indoor and outdoor coils are operating. This curve is only required when a reverse cycle defrost strategy is selected. The curve is normalized to a value of 1.0 at the rating point conditions.

Field: Minimum Outdoor Dry-Bulb Temperature for Compressor Operation

This numeric field defines the minimum outdoor air dry-bulb temperature where the heating coil compressor turns off. If this input field is left blank, the default value is -8 °C.

Field: Outdoor Dry-Bulb Temperature to Turn On Compressor

This numeric field defines the outdoor temperature when the compressor is automatically turned back on following an automatic shut off because of low outdoor dry-bulb temperature. This field is only used for the calculation of HSPF. If this field is not provided, then outdoor bin temperature used in the HSPF calculation is always considered to be greater than this temperature and 'Minimum Outdoor Dry-Bulb Temperature for Compressor Operation' field described above. This assumption is based on AHRI standard 210/240 (2008) and can introduce significant error in the final value of HSPF.

Field: Maximum Outdoor Dry-Bulb Temperature for Defrost Operation

This numeric field defines the outdoor air dry-bulb temperature above which outdoor coil defrosting is disabled. The temperature for this input field must be greater than or equal to 0 °C and less than or equal to 7.22 °C. If this input field is left blank, the default value is 5 °C.

Field: Crankcase Heater Capacity

This numeric field defines the crankcase heater capacity in Watts. When the outdoor air drybulb temperature is below the value specified in the input field "Maximum Outdoor Dry-bulb Temperature for Crankcase Heater Operation" (described below), the crankcase heater is enabled during the time that the compressor is not running. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0. To simulate a unit without a crankcase heater, enter a value of 0.

Field: Maximum Outdoor Dry-Bulb Temperature for Crankcase Heater Operation

This numeric field defines the outdoor air dry-bulb temperature above which the compressor's crankcase heater is disabled. The value for this input field must be greater than or equal to 0.0 °C. If this input field is left blank, the default value is 10 °C.

Field: Defrost Strategy

This alpha field has two choices: reverse-cycle or resistive. If the reverse-cycle strategy is selected, the heating cycle is reversed periodically to provide heat to melt frost accumulated on the outdoor coil. If a resistive defrost strategy is selected, the frost is melted using an electric resistance heater. If this input field is left blank, the default defrost strategy is reverse cycle.

Field: Defrost Control

This alpha field has two choices: timed or on-demand. If timed control is selected, the defrost time period is calculated based on a fixed value or compressor runtime whether or not frost has actually accumulated. For timed defrost control, the fractional amount of time the unit is in defrost is entered in the input field "Defrost Time Period Fraction" described below. If on-demand defrost control is selected, the defrost time period is calculated based on outdoor

weather (humidity ratio) conditions. Regardless of which defrost control is selected, defrost does not occur above the user specified outdoor temperature entered in the input field “Maximum Outdoor Dry-bulb Temperature for Defrost Operation” described above. If this input field is left blank, the default defrost control is timed.

Field: Defrost Time Period Fraction

This numeric field defines the fraction of compressor runtime when the defrost cycle is active, and only applies to “timed” defrost (see Defrost Control input field above). For example, if the defrost cycle is active for 3.5 minutes for every 60 minutes of compressor runtime, then the user should enter $3.5/60 = 0.058333$. The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.058333.

Field: Resistive Defrost Heater Capacity

This numeric field defines the capacity of the resistive defrost heating element in Watts. This input field is used only when the selected defrost strategy is ‘resistive’ (see input field “Defrost Strategy” above). The value for this input field must be greater than or equal to 0. If this input field is left blank, the default value is 0.

Field Group: Rated specification and performance curves

The performance for each heating speed must be specified as shown below. They should be directly given from the Reference Unit data. All inputs for Speed 1 are required, followed by the optional inputs for other speeds.

Field: Speed <x> Reference Unit Total Heating Capacity

This numeric field defines the total, full load heating capacity in watts of the air-to-air heating coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. Capacity should not include supply air fan heat.

Field: Speed <x> Reference Unit COP

This numeric field defines the coefficient of performance (COP=heating capacity output in watts divided by electrical power input in watts) of the heating coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The input power includes power for the compressor(s) and accessories, but does not include the power consumption of the indoor supply air fan.

Field: Speed <x> Reference Unit Volumetric Air Flow Rate

This numeric field defines the volume air flow rate, in m^3 per second, across the heating coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given heating capacity and COP at the speed, as above.

Field: Speed <x> Total Heating Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total heating capacity as a function of the indoor dry-bulb and source side entering air temperature, from the Reference Unit. The output of this curve is multiplied by the rated total heating capacity at the speed to give the total heating capacity at specific temperature operating conditions (i.e., at an indoor air dry-bulb temperature or entering air temperature different from the rating point temperature). It should be noted that the curve is normalized to the heating capacity at Speed<x> from the Reference Unit data, and have the value of 1.0 at the rating point.

Field: Speed <x> Total Heating Capacity Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of total heating capacity as a function of the ratio of actual air flow rate across the heating coil to the design air flow rate

(i.e., fraction of full load flow), at Speed $<x>$ from the Reference Unit data. The curve is normalized to have the value of 1.0 when the actual air flow rate equals the design air flow rate at Speed $<x>$.

Field: Speed $<x>$ Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve for Speed $<x>$ (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor air dry-bulb and entering air temperatures. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP at Speed $<x>$ from the Reference Unit data) to give the EIR at specific temperature operating conditions (i.e., at an indoor air dry bulb temperature or entering air temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed $<x>$ Energy Input Ratio Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed $<x>$ (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the heating coil to the design air flow rate (i.e., fraction of full load flow, at Speed $<x>$ from the Reference Unit data). The EIR is the inverse of the COP. This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

An example of this statement in an IDF is:

VSAirtoAirHP Power [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

VSAirtoAirHP Load Side Total Heat Transfer Rate [W]

The output variable is the average total heating capacity provide by the heat pump in Watts over the timestep being reported.

VSAirtoAirHP Load Side Sensible Heat Transfer Rate [W]

The output variable is the average sensible heating capacity provide by the heat pump in Watts over the timestep being reported. For heating mode, the sensible capacity is equal to the total capacity.

VSAirtoAirHP Source Side Total Heat Transfer Rate [W]

The output variable is the average heat absorbed at the heat pump evaporator in Watts over the timestep being reported.

VSAirtoAirHP Part-Load Ratio []

This output variable is the ratio of the part-load capacity to the steady state capacity of the heating coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the heating coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

VSAirtoAirHP Duty Factor []

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

VSAirtoAirHP Load Side Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

VSAirtoAirHP Load Side Inlet Dry Bulb Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

VSAirtoAirHP Load Side Inlet Humidity Ratio [kg/kg]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

VSAirtoAirHP Load Side Outlet Dry Bulb Temperature [C]

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

VSAirtoAirHP Load Side Outlet Humidity Ratio [kg/kg]

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

VSAirtoAirHP Source Side Mass Flow Rate [kg/s]

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

VSAirtoAirHP Source Side Inlet Temperature [C]

The output variable is the average entering water temperature over the timestep being reported.

VSAirtoAirHP Source Side Outlet Temperature [C]

The output variable is the average leaving water temperature over the timestep being reported.

VSAirtoAirHP Upper Speed Level []

The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

VSAirtoAirHP Speed Ratio between Two Neighboring Speeds []

The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

VSAirtoAirHP Recoverable Waste Heat [W]

This output variable is the average recoverable waste heat rate of the heat pump in Watts over the timestep being reported.

VSAirtoAirHP Heating Electric Consumption [J]

The output variable is the total electric consumption of the heat pump in Joules over the timestep being reported.

VSAirtoAirHP Load Side Total Heating Energy [J]

The output variable is the total cooling output of the coil in Joules over the timestep being reported.

VSAirtoAirHP Source Side Heating Energy [J]

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

VSAirtoAirHP Heating Coil Electric Defrost Power[W]

The output variable is the average electric power used for defrosting, in Watts over the timestep being reported.

VSAirtoAirHP Heating Coil Electric Defrost Consumption [J]

The output variable is the total electric defrosting energy usage of the coil in Joules over the timestep being reported.

VSAirtoAirHP Heating Coil Crankcase Heater Power [W]

The output variable is the average power used for crankcase heater, in Watts over the timestep being reported.

VSAirtoAirHP Heating Coil Crankcase Heater Consumption [J]

The output variable is the total electric energy usage of the coil for crankcase heater, in Joules over the timestep being reported.

Coil:WaterHeating:Desuperheater

A simplified approach is used to determine the performance of this water heating coil. The model assumes that the heating energy provided by this coil is reclaimed from the superheated refrigerant gas leaving a compressor (i.e., a desuperheating refrigerant-to-water heating coil) and does not impact the performance of the compressor. This coil must be used

with a water heater tank (e.g., Water Heater:Mixed) which can supply heated potable water and/or hot water for use in a plant loop (e.g., hydronic air reheat coils).

Except for detailed refrigeration system models, the amount of available superheat is simply a percentage of the total heat being rejected by the DX system's condenser. Approximately 25-30% of the energy rejected by typical refrigeration system condensers is to reduce the superheated refrigerant vapor temperature to the condensing temperature. Recovery efficiencies higher than 30% may cause the refrigerant gas to condense which in turn impacts the performance of the refrigeration system. For this reason, the maximum heat reclaim recovery efficiency for this coil is 30% for most sources of waste heat, including refrigeration compressor racks. The one exception to this 30% limit is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 90% of the heat within the superheated region.

The model includes the ability to modify the heat reclaim recovery efficiency based on variations in inlet water temperature and outdoor air dry-bulb temperature.

This coil model performs the following major functions:

- calculates the amount of heat delivered to the water tank
- calculates the electricity consumption of the integral water pump and on/off-cycle parasitic loads

The input fields for this object are described below in detail:

Field: Name

This alpha field contains a unique user-assigned name for an instance of a desuperheater water heating coil. Any reference to this desuperheater coil by another object will use this name.

Field: Availability Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that denotes whether the desuperheater coil is available to operate during a given time period. A schedule value equal to 0 denotes that the desuperheater coil is off for that time period. A value other than 0 denotes that the desuperheater coil is available to operate during that time period. During times when the desuperheater coil is scheduled off, the heater (element or burner) in the water tank object operates based on its tank set point temperature schedule and the desuperheater coil's parasitic electric power is also off for that time period.

Field: Setpoint Temperature Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that specifies the set point (or "cut-out") temperature for the desuperheater coil. Temperature values used in this schedule should be in degrees Celsius. The desuperheater coil turns off when the tank water reaches this set point temperature. Once the desuperheater coil is off, the tank water temperature floats downward until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the "cut-in" temperature). At this point, the desuperheater coil turns on and remains on until the desuperheater coil set point temperature is reached.

Field: Dead Band Temperature Difference

This numeric field contains the dead band temperature difference in degrees Celsius. The desuperheater coil "cut-in" temperature is defined as the desuperheater coil set point temperature defined above minus this dead band temperature difference. The desuperheater coil turns on when the water temperature in the tank falls below the "cut-in" temperature. The desuperheater coil remains on until the water temperature in the tank rises above the desuperheater coil set point ("cut-out") temperature defined above. The dead band

temperature difference must be greater than 0°C and less than or equal to 20°C. If this field is left blank, the default value is 5°C.

Desuperheater water heating coils are typically used to offset energy consumption by the water tank's heater (element or burner). Therefore, the cut-in temperature for the desuperheater coil (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point temperature is greater than the cut-in temperature of the desuperheater coil, the model disables the desuperheater coil and the tank's heater is used to heat the water.

Field: Rated Heat Reclaim Recovery Efficiency

This numeric field defines the ratio of recovered waste heat from the superheated refrigerant gas to the total rejected waste heat from the heating source (as if no heat reclaim occurred). Input values must be greater than 0 up to a maximum value is 0.3 (with a defaults of 0.25) for most sources of waste heat, including refrigeration compressor racks. The one exception to this 0.3 limit is a source that is a condenser that is part of a detailed refrigeration system. In a detailed refrigeration system, the portion of the rejected heat that lies within the superheated region is explicitly calculated. Therefore, the desuperheater coils supplied by a condenser attached to a detailed refrigeration system are subject to a maximum reclaim recovery efficiency of 0.9. with a default value is 0.8.

Field: Rated Inlet Water Temperature

This numeric field defines the coil inlet water temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. Also see field "Heat Reclaim Efficiency Modifier Curve Name (function of temperature)" below.

Field: Rated Outdoor Air Temperature

This numeric field defines the outdoor air dry-bulb temperature, in degrees Celsius, that corresponds to the rated heat reclaim recovery efficiency. The outdoor air dry-bulb temperature impacts the desuperheater coil refrigerant temperature and the amount of heat available for reclaim. Also see field "Heat Reclaim Efficiency Modifier Curve Name(function of temperature)" below.

Field: Maximum Inlet Water Temperature for Heat Reclaim

This numeric field defines the maximum coil inlet water temperature in degrees Celsius. Any time the inlet water temperature to the desuperheater coil is above this maximum allowed temperature, heat reclaim is restricted so that the tank water does not exceed this temperature.

Field: Heat Reclaim Efficiency Function of Temperature Curve Name

This alpha field specifies the name of a bi-quadratic curve object (ref: Performance Curves) that defines the variation in heat reclaim efficiency as a function of inlet fluid (air and water) temperatures. The bi-quadratic curve uses the coil inlet water temperature and outdoor air dry-bulb temperature (entering the DX coil condenser) as the independent variables. The output of this curve is multiplied by the rated heat reclaim recovery efficiency to give the heat reclaim efficiency at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heat reclaim efficiency remains constant (curve value assumed to be 1.0 for all conditions). The model restricts the product of the output of this curve and the rated heat reclaim recovery efficiency to a maximum of 0.9 for refrigeration condenser sources and 0.3 for all other sources..

Field: Water Inlet Node Name

This alpha field defines the name of the water node from which the desuperheater heating coil draws its inlet water. This node name must also match the source side outlet node name for the water heater tank used with this coil (ref. Water Heaters).

Field: Water Outlet Node Name

This alpha field defines the name of the water node to which the desuperheater heating coil sends its outlet water. This node name must also match the source side inlet node name for the water heater tank used with this coil (ref. Water Heaters).

Field: Tank Object Type

This alpha (choice) field contains the type of water heater tank used by this desuperheater heating coil. Currently, the only valid choice is Water Heater:Mixed.

Field: Tank Name

This alpha field contains the name of the specific water heater tank (Water Heater:Mixed object) used by this desuperheater heating coil.

Field: Heating Source Object Type

This alpha (choice) field defines the source of superheated refrigerant gas from which the desuperheater water heating coil recovers energy through heat reclaim. Valid choices are:

This alpha (choice) field defines the source of superheated refrigerant gas from which the desuperheater water heating coil recovers energy through heat reclaim. Valid choices are:

Coil:Cooling:DX:SingleSpeed
Coil:Cooling:DX:TwoSpeed
Coil:Cooling:DX:TwoStageWithHumidityControlMode
Refrigeration:CompressorRack
Refrigeration:Condenser:AirCooled
Refrigeration:Condenser:EvaporativeCooled
Refrigeration:Condenser:WaterCooled

Field: Heating Source Name

This alpha field defines the name of the desuperheater coil's heat source (e.g., the name of a specific coil of the type mentioned in the previous field which provides waste heat to this desuperheater water heating coil).

Field: Water Flow Rate

This numeric field defines the desuperheater coil's water flow rate in cubic meters per second. The model assumes that this flow rate is constant (throughout the simulation period) when the desuperheater coil operates, and that it corresponds to the heat reclaim recovery efficiency performance specified by the user. This water flow rate must be greater than zero.

Field: Water Pump Power

This numeric field defines the coil's water circulation pump power in Watts. This is the operating pump power as installed. Values must be greater than or equal to 0. If this field is left blank, the default value is 0. A warning message will be issued if the ratio of water pump power to desuperheater water volumetric flow rate exceeds 7.9264E6 W/m³/s, but the simulation will continue using the user-defined values. The model assumes that this integral pump (i.e., no need to define a separate pump object) cycles on and off with the desuperheater heating coil.

Field: Fraction of Pump Heat to Water

This numeric field defines the fraction of water circulation pump heat that is transferred to the water. The pump is assumed to be downstream of the desuperheater water heating coil, and this field is used to determine the desuperheater water outlet temperature. Values must be

greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

Field: On-Cycle Parasitic Electric Load

This optional numeric field contains the on-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Field: Off-Cycle Parasitic Electric Load

This optional numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the desuperheater water heating coil. This parasitic electric load is consumed whenever the desuperheater coil is available but is not operating, and the model assumes that this parasitic power does not contribute to heating the water nor does it affect the zone air heat balance. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Following is an example input for a desuperheater water heating coil.

```

Desuperheater Part Load Ratio

This output field contains the part load ratio of the desuperheater heating coil for the timestep being reported. This ratio represents the fraction of the timestep that the desuperheater heating coil is operating.

Desuperheater Water Heating Rate [W]

This output field contains the average heating rate output of the desuperheater heating coil in Watts for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

Desuperheater Water Heating Energy [J]

This output field contains the total heating output of the desuperheater heating coil in Joules for the timestep being reported. This value includes the portion of circulation pump heat attributed to heating the water.

Desuperheater Pump Electric Power [W]

This output field contains the average electricity consumption rate for the water circulation pump in Watts for the timestep being reported.

Desuperheater Pump Electric Consumption [J]

This output field contains the electricity consumption of the water circulation pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key= DHW, Group Key= Plant (ref. Report Meter).

Desuperheater Heat Reclaim Efficiency Modifier Curve Output

This output field contains the average output of the Heat Reclaim Efficiency Modifier Curve (function of temperature) for the timestep being reported.

Desuperheater On-Cycle Parasitic Electric Power [W]**Desuperheater On-Cycle Parasitic Electric Consumption [J]****Desuperheater Off-Cycle Parasitic Electric Power [W]****Desuperheater Off-Cycle Parasitic Electric Consumption [J]**

These outputs are the parasitic electric power and consumption associated with the desuperheater water heating coil. Specific outputs represent parasitic electrical usage during the coil on and off cycles. These outputs represent electronic controls or other electric component. The model assumes that the parasitic power does not contribute to heating the water nor does it impact the zone air heat balance. The parasitic electric consumption outputs are also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

CoilSystem:Cooling:DX

The CoilSystem:Cooling:DX object is a “virtual” container component that consists of a DX cooling coil component and its associated controls, as shown in the Figure below. This control object supports several different types of DX cooling coils (see field Cooling Coil Object Type).

This component may be used as a cooling coil in constant volume or variable volume systems, as blow through or draw through, with or without humidity controls. Unlike AirLoopHVAC:Unitary system types, this component controls only the DX coil, not the supply fan. CoilSystem:Cooling:DX is added to a system by placing it in an air loop branch (see Branch object) or in an AirLoopHVAC:OutdoorAirSystem:EquipmentList or in a ZoneHVAC:OutdoorAirUnit:EquipmentList . It requires one or more setpoint manager (see SetpointManager:*) objects to specify temperature and/or humidity setpoints (unless it is used in a ZoneHVAC:OutdoorAirUnit which has its own temperature setpoints). This object is the

one that is listed in the Branch or equipment list object rather than the coil itself. A constant volume or variable volume fan is modeled separately from this cooling system. These are the only fan types allowed for this system type (ref. Fan:ConstantVolume and Fan:VariableVolume). Cycling fan operation is not available with this model.

Figure 125. Schematic of CoilSystem:Cooling:DX Object in an Air Loop for a Blow Through Application

Field: Name

This alpha field contains the identifying name for this component.

Field: Availability Schedule Name

This alpha field contains the schedule name that contains information on the availability of the DX coil to operate.

Field: DX Cooling Coil System Inlet Node Name

This alpha field contains the identifying name given to the DX cooling coil inlet node, as specified in the DX cooling coil object.

Field: DX Cooling Coil System Outlet Node Name

This alpha field contains the identifying name given to the DX cooling coil outlet node, as specified in the cooling coil object.

Field: DX Cooling Coil System Sensor Node Name

This alpha field contains the identifying name given to the DX cooling coil control node, this is the node at which the temperature set point is specified by the set point manager.

Field: Cooling Coil Object Type

This alpha field specifies the type of DX cooling coil. The valid choices for this field are:

Coil:Cooling:DX:SingleSpeed
CoilSystem:Cooling:DX:HeatExchangerAssisted
Coil:Cooling:DX:TwoSpeed

Coil:Cooling:DX:TwoStageWithHumidityControlMode

Field: Cooling Coil Name

This alpha field contains the identifying name of the DX cooling coil.

As shown in the example below, correct specification of this system requires specification of the DX Cooling Coil object in addition to the CoilSystem:Cooling:DX object.

Field: Dehumidification Control Type

This alpha field contains the type of dehumidification control. The following options are valid for this field:

None - meet sensible load only, no active dehumidification control

MultiMode - activate enhanced dehumidification mode as needed and operate to meet the sensible load. If a sensible load exists, the system will operate to meet that sensible load and may not meet the latent load. If no sensible load exists, and Run on Latent Load = Yes, the system will operate to meet the entire latent load. This option is used to model DX equipment with a switchable option such as subcool reheat. It is valid only with Cooling coil type=Coil:Cooling:DX:TwoStageWithHumidityControlMode or CoilSystem:Cooling:DX:HeatExchangerAssisted. If the Run on Latent Load option below is set to Yes, this option may require the use of a heating coil and heating coil outlet air temperature set point manager downstream of this cooling coil to maintain the temperature set point.

CoolReheat - cool beyond the dry-bulb setpoint as required to meet the humidity setpoint. It is valid only with Cooling coil type=Coil:Cooling:DX:TwoStageWithHumidityControlMode. This option requires the use of a heating coil and heating coil outlet air temperature set point manager downstream of this cooling coil to maintain the temperature set point.

The default is **None**. For all dehumidification controls, the max humidity setpoint on the control node is used. This must be set using a **ZoneControl:Humidistat** **ZoneControl:Humidistat** and one of:

- **SetpointManager:SingleZone:Humidity:Maximum**
- **SetpointManager:MultiZone:Humidity:Maximum**
- **SetpointManager:MultiZone:MaximumHumidity:Average**

objects and **SetpointManager:OutdoorAirPretreat** (optional) objects. When extra dehumidification is required, the equipment may not be able to meet the humidity setpoint if its full capacity is not adequate.

Field: Run on Sensible Load

This alpha field specifies if the unit will operate to meet a sensible load as determined by the inlet node dry-bulb temperature and the dry-bulb temperature setpoint on the control node. There are two valid choices, **Yes** or **No**. If **Yes**, unit will run if there is a sensible load. If **No**, unit will not run if there is only a sensible load. The default is **Yes**.

Field: Run on Latent Load

This alpha field specifies if the unit will operate to meet a latent load as determined by the inlet node humidity ratio and the max humidity setpoint on the control node. There are two valid choices, **Yes** or **No**. If **Yes**, unit will run if there is a latent load. If both a sensible and latent load exist, the system will operate to maintain the temperature set point. When only a latent load exists, the system will operate to meet the humidity ratio set point and requires the use of a heating coil and heating coil outlet air temperature set point manager downstream of this cooling coil to maintain the temperature set point. If **No**, unit will not run if there is only a latent load. The default is **No**.

CoilSystem:Cooling:DX Outputs

Coil Type= Coil:Cooling:DX:TwoStageWithHumidityControlMode
HVAC,Average,Coil System Cycling Part Load Ratio
HVAC,Average,Coil System Compressor Speed Ratio
Coil types=Coil:Cooling:DX:SingleSpeed &
CoilSystem:Cooling:DX:HeatExchangerAssisted
HVAC,Average,Coil System Part Load Ratio

Coil System Cycling Part Load Ratio

The system may operate for the entire system timestep, but to meet the load the compressor can cycle on and off. This reports the fraction of the system timestep that the compressor is operating. (1.0 is continuous, 0.0 is off).

Coil System Compressor Speed Ratio

This is the ratio of time in a system timestep that the compressor is at rated speed. The compressor speed ratio reports (1.0 is max, 0.0 is min) and any value in between as it is averaged over the timestep.

Coil System Part Load Ratio

The DX system can operate with a cycling compressor or a varying speed compressor. This variable reports the fraction of the Full Load that is met during the system timestep. This can differ from the cycling part load ratio or the compressor speed ratio. (1.0 is Full Load and 0.0 is no load)

CoilSystem:Heating:DX

The CoilSystem:Heating:DX object is a “virtual” container component for a DX heating coil that provides the controls needed to operate the coil. Only single speed DX air-to-air heating coils are supported.

This component may be used as a heating coil in constant volume or variable volume air handlers. It can also be used in an outside air system (by including it in an AirLoopHVAC:OutdoorAirSystem:EquipmentList object) or in a zone outdoor air unit (by including it in an ZoneHVAC:OutdoorAirUnit:EquipmentList object). This object is the one that is listed in the Branch or equipment list object rather than the coil itself.

The inlet and outlet nodes for the DX heat pump system are defined in the heating coil object. The control node is always the outlet node of the coil. This DX heat pump heating system requires that a (drybulb) temperature setpoint be placed on the outlet node using either a setpoint manager or the energy management system. The coil is controlled to attempt to meet that setpoint using a part load ratio modeling approach.

This model only supports continuous fan and cycling compressor operation -- cycling fan modeling is not available with this model.

Field: Name

This alpha field contains the identifying name for this component.

Field: Availability Schedule Name

This alpha field contains the schedule name that contains information on the availability of the DX coil to operate.

Field: Heating Coil Object Type

This alpha field specifies the type of DX heating coil. This model currently supports only single speed DX heat pump heating coils and the only option for this field is Coil:Heating:DX:SingleSpeed.

Field: Heating Coil Name

This alpha field specifies the unique name of the DX heating coil. This field references the name of a Coil:Heating:DX:SingleSpeed that needs to be defined elsewhere in the input file.

An example of a DX heating coil system follows.

```

CoilSystem:Heating:DX Outputs

Coil System Part Load Ratio

The DX system can operate with a cycling compressor or a varying speed compressor. This variable reports the fraction of the Full Load that is met during the system timestep. This can differ from the cycling part load ratio or the compressor speed ratio. (1.0 is Full Load and 0.0 is no load)

CoilSystem:Cooling:DX:HeatExchangerAssisted

The heat exchanger-assisted DX cooling coil is a “virtual” component consisting of a direct expansion (DX) cooling coil and an air-to-air heat exchanger as shown in Figure 126 below. The air-to-air heat exchanger pre-conditions the air entering the cooling coil, and reuses this energy to post-condition the supply air leaving the cooling coil. This heat exchange process improves the latent removal performance of the cooling coil by allowing it to dedicate more of its cooling capacity toward dehumidification (lower sensible heat ratio).

This compound object models the basic operation of an air-to-air heat exchanger in conjunction with a cooling coil. The heat exchanger-assisted DX cooling coil does not have an operating schedule of its own; its operating schedule is governed by the availability schedules for the DX cooling coil and the air-to-air heat exchanger. This compound object is used in place of where a DX cooling coil object would normally be used by itself.

To model a heat exchanger-assisted DX cooling coil, the input data file should include the following objects:

- CoilSystem:Cooling:DX:HeatExchangerAssisted object
- Air-to-air heat exchanger object (HeatExchanger:AirToAir:FlatPlate, HeatExchanger:AirToAir:SensibleAndLatent, or HeatExchanger:Desiccant:BalancedFlow)
- DX cooling coil object (Coil:Cooling:DX:SingleSpeed)

In terms of controlling the operation of the heat exchanger, the heat exchanger is assumed to always provide its heat transfer when the associated DX cooling coil is operating and no high humidity control mechanism is specified. However, the heat exchanger’s energy transfer may be controlled (i.e., turned on and off) based on a zone air humidity level using either a humidistat (ref. AirLoopHVAC:Unitary:Furnace:HeatCool or AirLoopHVAC:UnitaryHeatCool) or a humidistat and a maximum humidity set point manager to place a humidity ratio set point on the appropriate control node (ref. CoilSystem:Cooling:DX). This model may also be used with the unitary changeover bypass system and the unitary air-to-air heat pump system (ref. AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass and AirLoopHVAC:UnitaryHeatPump:AirToAir); however, the heat exchanger is assumed to always provide its heat transfer when the cooling coil operates and cannot be turned on and off based on a zone air humidity set point. Two zone air conditioners may also use this model for improved dehumidification. The first type is the packaged terminal heat pump (ref. ZoneHVAC:PackagedTerminalHeatPump) where the heat exchanger’s heat transfer is always active whenever the cooling coil operates. The second type is the window air

conditioner (ref. ZoneHVAC:WindowAirConditioner) where the heat exchanger's heat transfer is always active when the cooling coil operates and no high humidity control mechanism is specified, OR the heat exchanger's heat transfer may be controlled based on zone air humidity level if a humidistat and high humidity set point manager are specified (maximum humidity ratio set point placed on the heat exchanger's exhaust air outlet node, ref. Figure 126).

Links to the cooling coil and air-to-air heat exchanger specifications are provided in the input data syntax for this compound object. A description of each input field for this compound object is provided below.

Figure 126. Schematic of the CoilSystem:Cooling:DX:HeatExchangerAssisted compound object

NOTE: Node naming shown in Figure 126 is representative for HeatExchanger:AirToAir:SensibleAndLatent. For HeatExchanger:AirToAir:FlatPlate, the exhaust air nodes are referred to as 'secondary air' nodes. For HeatExchanger:Desiccant:BalancedFlow, the supply air nodes are referred to as 'regeneration air' nodes and the exhaust air nodes as 'process air' nodes.

Field: Name

A unique user-assigned name for the heat exchanger-assisted DX cooling coil. Any reference to this compound component by another object will use this name.

Field: Heat Exchanger Object Type

This alpha field denotes the type of heat exchanger being modeled. Valid choices are:

HeatExchanger:AirToAir:FlatPlate
HeatExchanger:AirToAir:SensibleAndLatent
HeatExchanger:Desiccant:BalancedFlow

Field: Heat Exchanger Name

This alpha field denotes the name of the air-to-air heat exchanger being modeled.

Field: Cooling Coil Object Type

This alpha field denotes the type of DX cooling coil being modeled. The only valid choice is Coil:Cooling:DX:SingleSpeed.

Field: Cooling Coil Name

This alpha field denotes the name of the DX cooling coil being modeled.

```

CoilSystem:Cooling:DX:HeatExchangerAssisted Outputs

No variables are reported for this compound object. However, outputs are provided by the cooling coil and heat exchanger that are specified.

CoilSystem:Cooling:Water:HeatExchangerAssisted

The heat exchanger-assisted water cooling coil is a “virtual” component consisting of a chilled-water cooling coil and an air-to-air heat exchanger as shown in Figure 127 below. The air-to-air heat exchanger precools the air entering the cooling coil, and reuses this energy to reheat the supply air leaving the cooling coil. This heat exchange process improves the latent removal performance of the cooling coil by allowing it to dedicate more of its cooling capacity toward dehumidification (lower sensible heat ratio).

Figure 127. Schematic of the CoilSystem:Cooling:Water:HeatExchangerAssisted compound object

Note: Node naming shown in Figure 127 is representative for HeatExchanger:AirToAir:SensibleAndLatent. For HeatExchanger:AirToAir:FlatPlate, the exhaust air nodes are referred to as 'secondary air' nodes.

This compound object models the basic operation of an air-to-air heat exchanger in conjunction with a chilled-water cooling coil. The heat exchanger-assisted water cooling coil does not have an operating schedule of its own; its operating schedule is governed by the availability schedules for the chilled-water cooling coil and the air-to-air heat exchanger. Heat exchange will occur whenever the heat exchanger is available to operate (via its availability schedule) and a temperature difference exists between the two air streams -- there is currently no method to enable or disable heat exchange based on zone air humidity level. This compound object is used in place of where a chilled-water cooling coil object would normally be used by itself.

To model a heat exchanger-assisted water cooling coil, the input data file should include the following objects:

- CoilSystem:Cooling:Water:HeatExchangerAssisted compound object
- Air-to-air heat exchanger object (HeatExchanger:AirToAir:FlatPlate or HeatExchanger:AirToAir:SensibleAndLatent)
- Chilled-water cooling coil object (Coil:Cooling:Water or Coil:Cooling:Water:DetailedGeometry)

Links to the cooling coil and air-to-air heat exchanger specifications are provided in the input data syntax for this compound object. A description of each input field for this compound object is provided below.

Field: Name

A unique user-assigned name for the heat exchanger-assisted water cooling coil. Any reference to this compound component by another object (e.g., ZoneHVAC:UnitVentilator, ZoneHVAC:FourPipeFanCoil, component in an air loop Branch object) will use this name.

Field: Heat Exchanger Object Type

This alpha field denotes the type of heat exchanger being modeled. Valid choices are:

```

CoilSystem:Cooling:Water:HeatExchangerAssisted Outputs

No variables are reported for this compound object. However, outputs are provided by the cooling coil and heat exchanger that are specified.

Coil:WaterHeating:AirToWaterHeatPump

EnergyPlus can model a heat pump water heater (HPWH) consisting of a water heater tank (e.g., WaterHeater:Mixed), a direct expansion (DX) “coil” (i.e., an air-to-water DX compression system which includes a water heating coil, air coil, compressor, and water pump), and a fan to provide air flow across the air coil associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source.

The WaterHeater:HeatPump compound object, water heater tank object (e.g., WaterHeater:Mixed), and fan object (e.g., Fan:OnOff) are defined elsewhere in this reference document. Coil:WaterHeating:AirToWaterHeatPump object described here models an air-to-water DX compression system to determine its air-side and water-side performance. This DX coil object calculates the air-side sensible and latent cooling capacity at the specific operating conditions for each simulation timestep, as well as the condenser's water-side temperature difference at a given condenser water flow rate.

The heat pump water heater DX coil model performs the following major functions:

- calculates the electric consumption of the DX compressor and water pump
- calculates the amount of heat delivered to the water tank
- calculates the electric consumption of the compressor's crankcase heater
- calculates the air-side performance of the DX coil

The input fields for this object are described below in detail:

Field: Name

This alpha field defines a unique user-assigned name for an instance of a heat pump water heater DX coil. Any reference to this coil by another object (e.g., WaterHeater:HeatPump) will use this name.

Field: Rated Heating Capacity

This numeric field defines the DX coil heating capacity in Watts at the rated evaporator inlet air temperatures, rated condenser inlet water temperature, rated evaporator air flow rate, and rated condenser water flow rate specified below. Values must be greater than 0. This value

represents water heating capacity, and it may or may not include the impact of condenser pump heat (see field Condenser Pump Heat Included in Rated Heating Capacity below).

Field: Rated COP

This numeric field defines the DX coil's water heating coefficient of performance (COP=water heating capacity in watts divided by electrical power input in watts) at rated conditions (rated inlet temperatures and flow rates specified below). This input not only determines the electric energy use of the heat pump DX coil, but also the amount of total air cooling provided by the evaporator. The rated COP includes compressor power, and may or may not include condenser pump power or evaporator fan power (see field Evaporator Fan Power Included in Rated COP and field Condenser Pump Power Included in Rated COP). Values must be greater than 0. If this field is left blank, the default value is 3.2.

Field: Rated Sensible Heat Ratio

This numeric field defines the air-side sensible heat ratio (SHR=sensible cooling capacity divided by total cooling capacity) of the DX coil at rated conditions (rated inlet temperatures and flow rates specified below). This value should not include the effect of evaporator fan heat. Values must be greater than or equal to 0.5, and less than or equal to 1.0. The default value is 0.85.

Field: Rated Evaporator Inlet Air Dry-Bulb Temperature

This numeric field defines the evaporator inlet air dry-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5°C. If this field is left blank, the default value is 19.7°C.

Field: Rated Evaporator Inlet Air Wet-Bulb Temperature

This numeric field defines the evaporator inlet air wet-bulb temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 5°C. If this field is left blank, the default value is 13.5°C.

Field: Rated Condenser Inlet Water Temperature

This numeric field defines the condenser inlet water temperature, in degrees Celsius, that corresponds to rated coil performance (heating capacity, COP and SHR). Values must be greater than 25°C. If this field is left blank, the default value is 57.5°C.

Field: Rated Evaporator Air Flow Rate

This numeric field defines the evaporator air volume flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = **autocalculate**), the default value is 5.035E-5 m³/s/W (31.25 cfm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated evaporator air volumetric flow rate, a zone sizing object is not required.

Field: Rated Condenser Water Flow Rate

This numeric field defines the condenser water volumetric flow rate in cubic meters per second at rated conditions. Values must be greater than 0. If this field is left blank or autocalculated (field value = **autocalculate**), the default value is 4.487E-8 m³/s/W (0.208 gpm/MBH) multiplied by the Rated Heating Capacity specified above. When autocalculating the rated condenser water volumetric flow rate, a zone sizing object is not required. A warning message will be issued if the ratio of Rated Condenser Water Volumetric Flow Rate to Rated Heating Capacity is less than 1.79405E-8 m³/s/W (0.083 gpm/MBH) or greater than 8.97024E-8 m³/s/W (0.417 gpm/MBH), but the simulation will continue.

Field: Evaporator Fan Power Included in Rated COP

This choice field specifies if evaporator fan power is included in the rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling

provided by the evaporator for each simulation timestep. If Yes is selected, the evaporator fan power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. If No is selected, it is assumed that the total heating power does not include evaporator fan power. If this field is left blank, the default is Yes. See the Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Field: Condenser Pump Power Included in Rated COP

This choice field specifies if condenser pump power is included in the rated COP defined above. This input impacts the calculation of compressor electric power which then impacts the total air cooling provided by the evaporator for each simulation timestep. If Yes is selected, the condenser pump power is subtracted from the total electric heating power when calculating total evaporator cooling capacity. If No is selected, it is assumed that the total heating power does not include the condenser pump. If this field is left blank, the default is No. See Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Field: Condenser Pump Heat Included in Rated Heating Capacity and Rated COP

This choice field specifies if condenser pump heat is included in the rated heating capacity and rated COP defined above. This input impacts the calculation of compressor electric power and total air cooling provided by the evaporator for each simulation timestep. If Yes is selected, the condenser pump heat is already included in the rated heating capacity and rated COP. If No is selected, it is assumed that the rated heating capacity and rated COP do not include the condenser pump heat, and pump heat is added to the total water heating capacity based on the Condenser Water Pump Power and Fraction of Condenser Pump Heat to Water fields below. If this field is left blank, the default is No. See Engineering Reference section for Coil:WaterHeating:AirToWaterHeatPump for further details.

Field: Condenser Water Pump Power

This numeric field defines the DX coil's condenser pump power in Watts. This is the operating pump power as installed. Values must be greater than or equal to 0. If this field is left blank, the default value is 0. A warning message will be issued if the ratio of Condenser Water Pump Power to Rated Heating Capacity exceeds 0.1422 W/W (41.67 Watts/MBH), but the simulation will continue.

Field: Fraction of Condenser Pump Heat to Water

This numeric field defines the fraction of condenser pump heat that is transferred to the condenser water. The pump is assumed to be downstream of the condenser water coil, and this field is used to determine the water temperature at the condenser outlet node when the field Condenser Pump Power Included in Rated Heating Capacity is set to No. Values must be greater than or equal to 0 and less than or equal to 1. If this field is left blank, the default value is 0.2.

Field: Evaporator Air Inlet Node Name

This alpha field defines the name of the air node from which the evaporator coil draws its inlet air.

Field: Evaporator Air Outlet Node Name

This alpha field defines the name of the air node to which the evaporator coil sends its outlet air.

Field: Condenser Water Inlet Node Name

This alpha field defines the name of the node from which the DX coil condenser draws its inlet water. This node name must also match the source side outlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

Field: Condenser Water Outlet Node Name

This alpha field defines the name of the node to which the heat pump condenser sends its outlet water. This node name must also match the source side inlet node name for the water heater tank connected to this DX coil (ref: Water Heaters).

Field: Crankcase Heater Capacity

This numeric field defines the compressor's crankcase heater capacity in Watts. The crankcase heater only operates when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation specified below.

Field: Maximum Ambient Temperature for Crankcase Heater Operation

This numeric field defines the maximum ambient temperature for crankcase heater operation in degree Celsius. The crankcase heater only operates when the air surrounding the compressor is below this maximum temperature value and the compressor is off. The ambient temperature surrounding the compressor is set by the Heat Pump:Water Heater parent object (field Compressor Location).

Field: Evaporator Air Temperature Type for Curve Objects

This choice field specifies the air temperature type used for the heating capacity and COP modifier curve objects below. The valid selections are Dry-bulb Temperature and Wet-bulb Temperature. If dry-bulb temperature is selected, the inlet air dry-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If wet-bulb temperature is selected, the inlet air wet-bulb temperature entering the heat pump DX coil and fan section is used to evaluate the curve objects. If this field is left blank and the following curve names are defined, the default value is wet-bulb temperature. If the following curve names are not defined, this field is not used.

Field: Heating Capacity Function of Temperature Curve Name

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated heating capacity to give the heating capacity at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all conditions).

Field: Heating Capacity Function of Air Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated heating capacity and the heating capacity modifier curve (function of temperature) to give the DX coil heating capacity at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all air flow rates).

Field: Heating Capacity Function of Water Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating capacity as a function of

the ratio of actual water flow rate through the condenser to the rated condenser water flow rate. The output of this curve is multiplied by the rated heating capacity and the output from the two other heating capacity modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating capacity at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating capacity remains constant (curve value assumed to be 1.0 for all water flow rates).

Field: Heating COP Function of Temperature Curve Name

This alpha field specifies the name of a **biquadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of inlet fluid (air and water) temperatures. The biquadratic curve uses evaporator inlet air temperature (dry-bulb or wet-bulb temperature based on the field Evaporator Air Temperature Type for Curve Objects defined above) and condenser inlet water temperature as the independent variables. The cubic curve uses evaporator inlet air (dry-bulb or wet-bulb) temperature as the independent variable. The output of this curve is multiplied by the rated COP to give the heating COP at specific operating conditions (i.e., at temperatures different from the rating point temperatures). The curve should be normalized to have the value of 1.0 at the rating point temperatures. If this field is left blank, the COP remains constant (curve value assumed to be 1.0 for all conditions).

Field: Heating COP Function of Air Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual air flow rate across the evaporator coil to the rated evaporator air flow rate. The output of this curve is multiplied by the rated COP and the heating COP modifier curve (function of temperature) to give the heating COP at the specific inlet fluid temperatures and air flow rate at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated evaporator air flow rate (air flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all air flow rates).

Field: Heating COP Function of Water Flow Fraction Curve Name

This alpha field specifies the name of a **quadratic** or **cubic** performance curve object (ref: Performance Curves) that defines the variation in DX coil heating COP as a function of the ratio of actual water flow rate through the condenser to the rated condenser water flow rate.. The output of this curve is multiplied by the rated COP and the output from the two other heating COP modifier curves (function of temperature and function of air flow fraction) to give the DX coil heating COP at the specific inlet fluid temperatures and flow rates at which the coil is operating. The curve should be normalized to have the value of 1.0 at the rated condenser water flow rate (water flow fraction of 1.0). If this field is left blank, the heating COP remains constant (curve value assumed to be 1.0 for all water flow rates).

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a **quadratic** or **cubic** performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the DX unit as a function of the part load ratio (PLR, sensible cooling load/steady-state sensible cooling capacity). The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling.

The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If PLF < 0.7 a warning message is issued, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF. If PLF < PLR, then a warning message is issued and the runtime fraction of the coil is limited to 1.0.

A typical part load fraction correlation for a conventional, single-speed DX cooling coil (e.g., residential unit) would be:

$$\text{PLF} = 0.85 + 0.15(\text{PLR})$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$\text{PLF} = 1.0 + 0.0(\text{PLR})$$

Following is an example input for the Coil:WaterHeating:AirToWaterHeatPump object.

DX Coil Total Cooling Rate[W]

This output field is the average total (sensible and latent) cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Total Cooling Energy[J]

This output field is the total (sensible plus latent) cooling output of the DX coil in Joules for the timestep being reported. This is determined by the coil inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Rate[W]

This output field is the average moist air sensible cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Sensible Cooling Energy[J]

This output field is the moist air sensible cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Rate[W]

This output field is the average latent cooling rate output of the DX coil in Watts for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Latent Cooling Energy[J]

This output field is the latent cooling output of the DX coil in Joules for the timestep being reported. This is determined by the inlet and outlet air conditions and the air mass flow rate through the coil.

DX Coil Runtime Fraction

This output field is the average runtime fraction of the DX coil compressor for the timestep being reported. This also represents the runtime fraction of the condenser water pump.

DX Coil Crankcase Heater Power[W]

This output field is the average electricity consumption rate of the DX coil compressor's crankcase heater in Watts for the timestep being reported. The crankcase heater operates only when the compressor is off and the air surrounding the compressor is below the Maximum Ambient Temperature for Crankcase Heater Operation, otherwise this output variable is set equal to 0.

DX Coil Crankcase Heater Consumption[J]

This output field is the total electricity consumption of the DX coil compressor's crankcase heater in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

DX Coil Total Water Heating Rate[W]

This output field is the average water heating rate output of the DX coil (condenser coil plus condenser water pump) in Watts for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

DX Coil Total Water Heating Energy[J]

This output field is the total water heating output of the DX coil (condenser coil plus condenser water pump) in Joules for the timestep being reported. This is determined using the inlet and outlet water temperatures and the water mass flow rate through the condenser coil.

DX Coil Water Heating Electric Power[W]

This output field is the average electricity consumption rate of the DX coil compressor and condenser pump in Watts for the timestep being reported.

DX Coil Water Heating Electric Consumption[J]

This output field is the electricity consumption of the DX coil compressor and condenser pump in Joules for the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

Coil:Cooling:WaterToAirHeatPump:ParameterEstimation

The **Coil:Cooling:WaterToAirHeatPump:ParameterEstimation** coil is a deterministic model that requires parameters to describe the operating conditions of the heat pump's components. The parameters are generated from the manufacturer catalog data using multi-variable optimization method. In addition, the cooling coil model can be used for 3 type of compressors: **reciprocating**, **rotary** and **scroll**. Descriptions and strength of each respective model is available in the following references:

Jin, Hui. 2002. Parameter Estimation Based Models of Water Source Heat Pumps. Phd. Thesis, Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Tang,C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Field: Name

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., AirLoopHVAC:UnitaryHeatPump:WaterToAir) will use this name.

Field: Compressor Type

Type of compressor mode used for the heat pump. Choices available are reciprocating, rotary and scroll compressor. Note that the parameters vary for different compressor.

Field: Refrigerant Type

This alpha field contains the type of refrigerant used by the heat pump.

Field: Design Source Side Flow Rate

This numeric field defines the water flow rate though the coil in m³/sec

Field: Nominal Cooling Coil Capacity

This numeric field defines the nominal cooling capacity for the WatertoAirHP cooling coil in Watts.

Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity

(Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: High Pressure Cutoff

This numeric field defines the compressor's maximum allowable pressure in Pascal (N/m²)

Field: Low Pressure Cutoff

This numeric field defines the compressor's minimum allowable pressure in Pascal (N/m²)

Field: Water Inlet Node Name

This alpha field contains the cooling coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the cooling coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the cooling coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the cooling coil air outlet node name.

Cooling Coil Parameters

Depending on the type of compressor and the source side fluid specified, the type of parameters and values also differs. An Excel Spreadsheet is developed to estimate the parameters based on the manufacturer data. The general parameters are listed first followed by specific parameters required by the respective compressor model. Lastly, parameters are listed based on the type of source side fluid used.

Field: Load Side Total Heat Transfer Coefficient

This numeric field defines the estimated parameter **load side total heat transfer coefficient** in W/K. This field was previously known as Parameter 1.

Field: Load Side Outside Surface Heat Transfer Coefficient

This numeric field defines the estimated parameter **load side outside surface heat transfer coefficient** in W/K. This field was previously known as Parameter 2.

Field: Superheat Temperature at the Evaporator Outlet

This numeric field defines the estimated parameter **superheat temperature** at the evaporator outlet in °C. This field was previously known as Parameter 3.

Field: Compressor Power Losses

This numeric field defines the estimated parameter **compressor power losses**, which accounts for the loss of work due to mechanical and electrical losses in the compressor in Watts. This field was previously known as Parameter 4.

Field: Compressor Efficiency

This numeric field defines the estimated parameter of the **compressor's efficiency**. The compressor efficiency is formulated as the equation below:

$$\eta = \frac{\dot{W}_{Theoretical}}{\dot{W}_{CompInput} - \dot{W}_{Loss}}$$

This field was previously know as Parameter 5.

Field: Compressor Piston Displacement

This numeric field defines the estimated parameter **piston displacement of the compressor** in m³/s. This field was part of what was previously known as Parameter 6. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

Field: Compressor Suction/Discharge Pressure Drop

This numeric field defines the estimated parameter **pressure drop** at the compressor suction and discharge in Pascals (N/m²). This field was part of what was previously known as Parameter 7. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

Field: Compressor Clearance Factor

This numeric field defines the estimated parameter **clearance factor of the compressor**. This parameter is dimensionless. This field was part of what was previously known as Parameter 8. It should only be used when the Compressor type is Reciprocating. The field should be left blank when Compressor type is Scroll or Rotary.

Field: Refrigerant Volume Flow Rate

This numeric field defines the **refrigerant volume flow rate** at the beginning of the compression [m³/s]. This field was part of what was previously known as Parameter 6. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

Field: Volume Ratio

This numeric field defines the **built-in-volume ratio**. This field was part of what was previously known as Parameter 7. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

Field: Leak Rate Coefficient

This numeric field defines the **leak rate coefficient** for the relationship between pressure ratio and leakage rate. This field was part of what was previously known as Parameter 8. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

Field: Source Side Heat Transfer Coefficient

This numeric field defines the estimated parameter **source side heat transfer coefficient** in W/K. This field was part of what was previously known as Parameter 9. It should only be used when the Source Side Fluid Name is Water.

Field: Source Side Heat Transfer Resistance1

This numeric field defines the estimated parameter **source side heat transfer resistance 1**. Unit is dimensionless. This field was part of what was previously known as Parameter 9. It should only be used when the Source Side Fluid Name is an antifreeze.

Field: Source Side Heat Transfer Resistance2

This numeric field defines the estimated parameter **source side heat transfer resistance 2**. Unit is W/K. This field was previously known as Parameter 10. It should only be used when the Source Side Fluid Name is an antifreeze.

Coil:Cooling:WaterToAirHeatPump:EquationFit

The Coil:Cooling:WaterToAirHeatPump:EquationFit is a simple curve-fit model that requires coefficients generated from the heat pump catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data. Description of the equation-fit model is available in the following reference:

Tang,C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Field: Name

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., AirLoopHVAC:UnitaryHeatPump:WaterToAir) will use this name.

Field: Water Inlet Node Name

This alpha field contains the cooling coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the cooling coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the cooling coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the cooling coil air outlet node name.

Field: Rated Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump in m³/s. This field is autosizable.

Field: Rated Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump in m³/s. This field is autosizable.

Field: Rated Total Cooling Capacity

This numeric field contains the rated total cooling capacity of the heat pump in W. This field is autosizable. The rated total cooling capacity should be within 20% of the rated heating capacity, otherwise a warning message is issued.

Field: Rated Sensible Cooling Capacity

This numeric field contains the rated sensible capacity of the heat pump in W. This field is autosizable.

Field: Rated Cooling Coefficient of Performance

This numeric field contains the rated cooling coefficient of performance of the heat pump.

Field: Total Cooling Capacity Coefficient 1 to 5

These numeric fields contain the first to fifth coefficient for the heat pump total cooling capacity.

Field: Sensible Cooling Capacity Coefficient 1 to 6

These numeric fields contain the first to sixth coefficient for the heat pump sensible cooling capacity.

Field: Cooling Power Consumption Coefficient 1 to 5

These numeric fields contain the first to fifth coefficient for the heat pump power consumption.

Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

HVAC, Sum, WatertoAirHP Load Side Latent Cooling Energy [J]
HVAC, Sum, WatertoAirHP Source Side Cooling Energy [J]

```

WatertoAirHP Power [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

WatertoAirHP Load Side Total Heat Transfer Rate [W]

The output variable is the average total cooling load provide by the heat pump which includes the sensible and latent load in Watts over the timestep being reported.

WatertoAirHP Load Side Sensible Heat Transfer Rate [W]

The output variable is the average sensible cooling load provide by the heat pump in Watts over the timestep being reported.

WatertoAirHP Source Side Total Heat Transfer Rate [W]

The output variable is the average heat rejected to the water at the heat pump condenser in Watts over the timestep being reported.

WatertoAirHP Part-Load Ratio

This output variable is the ratio of the part-load capacity to the steady state capacity of the WatertoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the WatertoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

WatertoAirHP Duty Factor

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

WatertoAirHP Load Side Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

WatertoAirHP Load Side Inlet Dry Bulb Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

WatertoAirHP Load Side Inlet Humidity Ratio [kg/kg]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

WatertoAirHP Load Side Outlet Dry Bulb Temperature [C]

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

WatertoAirHP Load Side Outlet Humidity Ratio [kg/kg]

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

WatertoAirHP Source Side Mass Flow Rate [kg/s]

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

WatertoAirHP Source Side Inlet Temperature [C]

The output variable is the average entering water temperature over the timestep being reported.

WatertoAirHP Source Side Outlet Temperature [C]

The output variable is the average leaving water temperature over the timestep being reported.

WatertoAirHP Cooling Electric Consumption [J]

The output variable is the electric consumption of the heat pump in Joules over the timestep being reported. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Cooling, Group Key = System (ref. Report Meter).

WatertoAirHP Load Side Total Cooling Energy [J]

The output variable is the total cooling output of the coil in Joules over the timestep being reported. Resource Type = EnergyTransfer, End Use Key = CoolingCoils, Group Key = System (ref. Report Meter).

WatertoAirHP Load Side Sensible Cooling Energy [J]

The output variable is the total sensible cooling output of the coil in Joules over the timestep being reported

WatertoAirHP Load Side Latent Cooling Energy [J]

The output variable is the total latent cooling output of the coil in Joules over the timestep being reported.

WatertoAirHP Source Side Cooling Energy [J]

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported

Coil:Cooling:WaterToAirHeatPump:VariableSpeedEquationFit

The Variable-Speed Water-to-Air Cooling Equation Fit Coil is a collection of performance curves that represent the cooling coil at various speed levels. The performance curves should be generated from the heat pump Reference Unit data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. On the other hand, the model uses the bypass factor approach to calculate sensible heat transfer rate, similar to the one used in the single-speed DX coil. The number of speed levels can range from 2 to 10. The cooling coil has four node connections, i.e. two air sides and two water sides. The user needs to specify a nominal speed level, at which the rated total cooling capacity, rated volumetric air and water flow rates are sized. The rated capacity, rated volumetric flow rates represent the real situation in the air and water loops, and are used to determine and flow rates at various speed levels in the parent objects, e.g. AirLoopHVAC:UnitaryHeatPump:WaterToAir and ZoneHVAC:WaterToAirHeatPump. It shall be mentioned that the performance correction curves, i.e. the temperature and flow fraction correction curves, should be normalized to the capacity and flow rates at each individual speed and at the rated conditions, similar to the performance curves used in the DX coils. However, the performance values, e.g. capacities, COPs, SHRs and flow rates at individual speed levels, should be given regarding a specific unit from the Reference Unit catalog data. In the following content, the statement started with “Reference Unit” means the actual Reference Unit catalog data. The rated conditions for obtaining the capacities, COPs and SHRs are at indoor dry-bulb temperature of 26.67 °C (80 °F), wet bulb temperature of 19.44 °C (67 °F), and the source side entering water temperature of 29.4 °C (85 °F). Some equations are provided below to help explain the function of the various performance curves and data fields. For a detailed description of the algorithm and how the curves are used in the calculations, please see the Engineering Reference.

Field: Name

This alpha field contains the identifying name for the variable speed cooling coil. Any reference to this coil by another object (e.g., AirLoopHVAC:UnitaryHeatPump:WaterToAir) will use this name.

Field: Water Inlet Node Name

This alpha field contains the cooling coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the cooling coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the cooling coil load side inlet node name.

Field: Air Outlet Node Name

This alpha field contains the cooling coil load side outlet node name.

Field: Number of Speeds

This numeric field contains the maximum number of speed levels that the module uses. The number of speeds, for which the user input the performance data and curves, should be equal or higher than the maximum number. The performance inputs at higher speed levels are ignored.

Field: Nominal Speed Level

This numeric field defines the nominal speed level, at which the rated capacity, rated air and water volumetric flow rates are correlated.

Field: Rated Total Cooling Capacity at Selected Nominal Speed Level

This numeric field contains the rated total cooling capacity at the nominal speed level. This field is autosizable. The rated total cooling capacity is used to determine a capacity scaling factor, as compared to the Reference Unit capacity at the nominal speed level.

$$\text{CapacityScaleFactor} = \frac{\text{Rated Total Cooling Capacity}}{\text{ReferenceUnit Capacity @ Nominal Speed Level}}$$

And then, this scaling factor is used to determine capacities at rated conditions for other speed levels, as below,

$$\begin{aligned} \text{Rated Capacity @ Speed Level}(x) &= \text{CapacityScaleFactor} \\ &\times \text{ReferenceUnit Capacity @ Speed Level}(x) \end{aligned}$$

Field: Rated Volumetric Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump corresponding to the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the air flow rates in the parent objects. It is recommended that the ratio of the rated volumetric air flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

AirFlowScaleFactor =

$$\frac{\text{Rated Volumetric Air Flow Rate}}{\text{Reference Unit Vol Air Flow Rate @ Nominal Speed Level} \times \text{CapacityScaleFactor}}$$

And the volumetric air flow rates in the parent objects are calculated as below,

$$\begin{aligned} \text{Loop Volumetric Air Flow Rate @ Speed Level}(x) &= \text{AirFlowScaleFactor} \\ &\times \text{Reference Unit Vol Air Flow Rate @ Speed Level}(x) \\ &\times \text{CapacityScaleFactor} \end{aligned}$$

Field: Rated Volumetric Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump at the nominal speed level. This field is autosizable. The value is used to determine an internal scaling factor, and calculate the water flow rates in the water loop. It is recommended that the ratio of the rated volumetric water flow rate to the rated capacity is the same as the unit performance from the Reference Unit data.

WaterFlowScaleFactor =

$$\frac{\text{Rated Volumetric Water Flow Rate}}{\text{Reference Unit Vol Water Flow Rate @ Nominal Speed Level} \times \text{CapacityScaleFactor}}$$

And the required volumetric water flow rates at the speed levels in the parent objects, other than the nominal speed, are calculated as below,

$$\begin{aligned} \text{Loop Volumetric Water Flow Rate @ Speed Level}(x) &= \text{WaterFlowScaleFactor} \\ &\times \text{Reference Unit Vol Water Flow Rate @ Speed Level}(x) \\ &\times \text{CapacityScaleFactor} \end{aligned}$$

Field: Nominal Time for Condensate Removal to Begin

This numeric field defines the nominal time (in seconds) after startup for condensate to begin leaving the coil's condensate drain line at the coil's rated airflow and temperature conditions, starting with a dry coil. Nominal time is equal to the ratio of the energy of the coil's maximum condensate holding capacity (J) to the coil's steady-state latent capacity (W). Suggested value is 1000; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Ratio of Initial Moisture Evaporation Rate and Steady State Latent Capacity

This numeric field defines ratio of the initial moisture evaporation rate from the cooling coil (when the compressor first turns off, in Watts) and the coil's steady-state latent capacity (Watts) at rated airflow and temperature conditions. Suggested value is 1.5; zero value means the latent degradation model is disabled. The default value for this field is zero.

Field: Flag for Using Hot Gas Reheat, 0 or 1

This numeric field dictates whether to use the recoverable waste heat for reheating the supply air, downstream of the coil. The value "1" means using the hot gas reheating, and "0" means not using. If the hot gas reheating is turned on, the recoverable waste heat is subtracted from both the total cooling capacity and the sensible cooling capacity. The default value for this field is zero.

Field: Part Load Fraction Correlation Curve Name

This alpha field defines the name of a quadratic or cubic performance curve (Ref: Performance Curves) that parameterizes the variation of electrical power input to the unit as a function of the part load ratio (PLR, sensible or latent load/steady-state sensible or latent cooling capacity for Speed 1), in the case that the unit operates under the lowest speed, i.e. on/off. The product of the rated EIR and EIR modifier curves is divided by the output of this curve to give the “effective” EIR for a given simulation timestep for Speed 1. The part load fraction (PLF) correlation accounts for efficiency losses due to compressor cycling. The part load fraction correlation should be normalized to a value of 1.0 when the part load ratio equals 1.0 (i.e., no efficiency losses when the compressor(s) run continuously for the simulation timestep). For PLR values between 0 and 1 ($0 \leq PLR < 1$), the following rules apply:

$$PLF \geq 0.7 \text{ and } PLF \geq PLR$$

If $PLF < 0.7$, the program resets the PLF value to 0.7, and the simulation proceeds. The runtime fraction of the coil is defined as PLR/PLF . If $PLF < PLR$, the runtime fraction of the coil is limited to 1.0. A typical part load fraction correlation would be:

$$PLF = 0.85 + 0.15 \times PLR$$

If the user wishes to model no efficiency degradation due to compressor cycling, the part load fraction correlation should be defined as follows:

$$PLF = 0.85 + 0.0 \times PLR$$

Field Group: rated specification, performance curves, and waste heat data

The performance for each cooling speed must be specified as shown below. They should be directly given from the Reference Unit catalog data. All inputs for Speed 1 and 2 are required, followed by the optional inputs for other speeds.

Field: Speed <x> Reference Unit Total Cooling Capacity

This numeric field defines the total, full load cooling capacity in watts of the water-to-air cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. Capacity should not include supply air fan heat.

Field: Speed <x> Reference Unit SHR

This numeric field defines sensible heat transfer ratio (SHR = sensible heat transfer rate divided by total cooling capacity) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0.0 and less than 1.0. This value should be obtained from the Reference Unit data.

Field: Speed <x> Reference Unit COP

This numeric field defines the coefficient of performance (COP=total cooling capacity output in watts divided by electrical power input in watts) of the cooling coil unit at rated conditions for Speed <x> operation. The value entered here must be greater than 0. The input power includes power for the compressor(s) and accessories, but does not include the power consumptions of the indoor supply air fan and water pump.

Field: Speed <x> Reference Unit Air Flow Rate

This numeric field defines the volumetric air flow rate, in m^3 per second, across the cooling coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given cooling capacity and COP at the speed, as above.

Field: Speed <x> Reference Unit Water Flow Rate

This numeric field defines the volumetric water flow rate, in m^3 per second, flowing at the source side of the cooling coil at rated conditions for Speed <x> operation. The value entered here should be directly from the Reference Unit data, corresponding to the given cooling capacity and COP at the speed, as above.

Field: Speed <x> Total Cooling Capacity Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the total cooling capacity as a function of the both the indoor wet-bulb and source side entering water temperature, from the Reference Unit. The output of this curve is multiplied by the rated total cooling capacity at the speed to give the total cooling capacity at specific temperature operating conditions (i.e., at an indoor air wet-bulb temperature or entering water temperature different from the rating point temperature). It should be noted that the curve is normalized to the cooling capacity at Speed<x> from the Reference Unit data, and have the value of 1.0 at the rating point.

Field: Speed <x> Total Cooling Capacity Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow at Speed <x>, from the Reference Unit data). The curve is normalized to have the value of 1.0 when the actual air flow rate equals the design air flow rate, at Speed <x>.

Field: Speed <x> Total Cooling Capacity Function of Water Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of total cooling capacity as a function of the ratio of actual water flow rate across the cooling coil to the design water flow rate (i.e., fraction of full load flow), at Speed <x>, from the Reference Unit data. The curve is normalized to have the value of 1.0 when the actual water flow rate equals the design air flow rate, at Speed <x>.

The actual total cooling capacity at Speed <x>, considering variations in temperatures, air and water flow rates is calculated as below:

$$\begin{aligned} \text{Actual Capacity @ Speed Level}(x) = & \text{CapacityScaleFactor} \\ & \times \text{ReferenceUnit Capacity @ Speed Level}(x) \\ & \times \text{TotCapTempModFac @ Speed Level}(x) \\ & \times \text{TotCapAirFlowModFac @ Speed Level}(x) \\ & \times \text{TotCapWaterFlowModFac @ Speed Level}(x) \end{aligned}$$

Field: Speed <x> Energy Input Ratio Function of Temperature Curve Name

This alpha field defines the name of a bi-quadratic, quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the both the indoor air wet-bulb and entering water temperatures. The EIR is the inverse of the COP. The output of this curve is multiplied by the rated EIR (inverse of rated COP at Speed <x> from the Reference Unit data) to give the EIR at specific temperature operating conditions (i.e., at an indoor air wet-bulb temperature or entering water temperature different from the rating point temperature). The curve is normalized to have the value of 1.0 at the rating point.

Field: Speed <x> Energy Input Ratio Function of Air Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual air flow rate across the cooling coil to the design air flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). The EIR is the inverse of the COP. This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

Field: Speed <x> Energy Input Ratio Function of Water Flow Fraction Curve Name

This alpha field defines the name of a quadratic or cubic performance curve for Speed <x> (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the ratio of actual water flow rate across the cooling coil to the design water flow rate (i.e., fraction of full load flow, at Speed <x> from the Reference Unit data). This curve is normalized to a value of 1.0 when the actual air flow rate equals the design air flow rate.

The actual EIR at Speed <x>, considering variations in temperatures, air and water flow rates is calculated as below:

$$\begin{aligned} \text{Actual EIR @ Speed Level}(x) = & \frac{1.0}{\text{ReferenceUnit COP @ Speed Level}(x)} \\ & \times \text{EIRTempModFac @ Speed Level}(x) \\ & \times \text{EIRAirFlowModFac @ Speed Level}(x) \\ & \times \text{EIRWaterFlowModFac @ Speed Level}(x) \end{aligned}$$

And, the actual power consumption is calculated:

$$\begin{aligned} \text{Actual Power @ Speed Level}(x) = & \text{Actual Capacity @ Speed Level}(x) \\ & \times \text{Actual EIR @ Speed Level}(x) \end{aligned}$$

Field: Speed <x> Reference Unit Waste Heat Fraction of Power Input

The fraction of heat input to cooling that is available as recoverable waste heat at full load and rated conditions for Speed <x> operation. The part of heat is not discharged to the water loop. And it can be used for hot gas reheating during dehumidification operation, by setting 1 to Flag for Using Hot Gas Reheat.

Field: Speed <x> Waste Heat Function of Temperature Curve Name

The name of a bi-quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the waste heat recovery as a function of indoor wet-bulb temperature and the entering water temperature for Speed <x> from the Reference Unit data. The output of this curve is multiplied by the design recoverable waste heat at specific temperature operating conditions (i.e., at temperatures different from the rating point). The curve is normalized to a value of 1.0 at the rating point.

The actual recoverable waste heat at Speed <x> is calculated as below:

$$\begin{aligned} \text{Actual Waste Heat @ Speed Level}(x) = & \text{Actual Power @ Speed Level}(x) \\ & \times \text{WasteHeatFrac @ Speed Level}(x) \\ & \times \text{WasteHeatTempModFac @ Speed Level}(x) \end{aligned}$$

An example of this statement in an IDF is:

VSWatertoAirHP Power [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

VSWatertoAirHP Load Side Total Heat Transfer Rate [W]

The output variable is the average total cooling load provide by the heat pump which includes the sensible and latent load in Watts over the timestep being reported.

VSWatertoAirHP Load Side Sensible Heat Transfer Rate [W]

The output variable is the average sensible cooling load provide by the heat pump in Watts over the timestep being reported.

VSWatertoAirHP Source Side Total Heat Transfer Rate [W]

The output variable is the average heat rejected to the water at the heat pump condenser in Watts over the timestep being reported.

VSWatertoAirHP Part-Load Ratio

This output variable is the ratio of the part-load capacity to the steady state capacity of the VSWatertoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the VSWatertoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

VSWatertoAirHP Duty Factor

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

VSWatertoAirHP Load Side Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

VSWatertoAirHP Load Side Inlet Dry Bulb Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

VSWatertoAirHP Load Side Inlet Humidity Ratio [kg/kg]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

VSWatertoAirHP Load Side Outlet Dry Bulb Temperature [C]

The output variable is the average leaving air dry-bulb temperature over the timestep being reported.

VSWatertoAirHP Load Side Outlet Humidity Ratio [kg/kg]

The output variable is the average leaving air dry humidity ratio over the timestep being reported.

VSWatertoAirHP Source Side Mass Flow Rate [kg/s]

The output variable is the average water mass flow rate going through the heat pump over the timestep being reported.

VSWatertoAirHP Source Side Inlet Temperature [C]

The output variable is the average entering water temperature over the timestep being reported.

VSWatertoAirHP Source Side Outlet Temperature [C]

The output variable is the average leaving water temperature over the timestep being reported.

VSWatertoAirHP Upper Speed Level [Dimensionless]

The output variable is the average upper speed level, for interpolating performances between two neighboring speed levels.

VSWatertoAirHP Speed Ratio between Two Neighboring Speeds [Dimensionless]

The output variable is the average speed ratio, for interpolating performances between two neighboring speed levels.

VSWatertoAirHP Recoverable Waste Heat [W]

This output variable is the average recoverable waste heat rate of the heat pump in Watts over the timestep being reported.

VSWatertoAirHP Cooling Electric Consumption [J]

The output variable is the electric consumption of the heat pump in Joules over the timestep being reported.

VSWatertoAirHP Load Side Total Cooling Energy [J]

The output variable is the total cooling output of the coil in Joules over the timestep being reported.

VSWatertoAirHP Load Side Sensible Cooling Energy [J]

The output variable is the total sensible cooling output of the coil in Joules over the timestep being reported

VSWatertoAirHP Load Side Latent Cooling Energy [J]

The output variable is the total latent cooling output of the coil in Joules over the timestep being reported.

VSWatertoAirHP Source Side Cooling Energy [J]

The output variable is the total source side heat transfer of the coil in Joules over the timestep being reported.

Coil:Heating:WaterToAirHeatPump:ParameterEstimation

The Water to Air heat pump heating coil is a deterministic model that requires parameters to describe the operating conditions of the heat pump's components. The parameters are generated from the manufacturer catalog data using multi-variable optimization method. However, the parameters required for WatertoAirHP heating coil is similar to WatertoAirHP cooling except (source side outside heat transfer coefficient) parameter is not required for heating. In addition, the heating coil model can be used for 3 type of compressors which are **reciprocating, rotary and scroll**.

Field: Name

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., AirLoopHVAC:UnitaryHeatPump:WaterToAir) will use this name.

Field: Compressor Type

Type of compressor mode used for the heat pump. Choices available are reciprocating, rotary and scroll compressor. Note that the parameters vary for different compressor.

Field: Refrigerant Type

This alpha field contains the type of refrigerant used by the heat pump.

Field: Design Source Side Flow Rate

This numeric field defines the water flow rate though the coil in m³/sec

Field: Nominal Heating Coil Capacity

This numeric field defines the nominal heating capacity for the WatertoAirHP heating coil in Watts.

Field: High Pressure Cutoff

This numeric field defines the compressor's maximum allowable pressure in Pascal (N/m²)

Field: Low Pressure Cutoff

This numeric field defines the compressor's minimum allowable pressure in Pascal (N/m²)

Field: Water Inlet Node Name

This alpha field contains the heating coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the heating coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the heating coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the heating coil air outlet node name.

Heating Coil Parameters

Depending on the type of compressor specified, the type of parameters and values also differs. An Excel Spreadsheet is in the final stage of development that is capable of estimating the parameters based on the manufacturer data. The general parameters are listed first followed by specific parameters required by the respective compressor model. Lastly, parameters are listed based on the type of source side fluid used.

Field: Load Side Total Heat Transfer Coefficient

This numeric field defines the estimated parameter **load side total heat transfer coefficient** in W/K. This field was previously known as Parameter 1.

Field: Superheat Temperature at the Evaporator Outlet

This numeric field defines the estimated parameter **superheat temperature** at the evaporator outlet in °C. This field was previously known as Parameter 2.

Field: Compressor Power Losses

This numeric field defines the estimated parameter **compressor power losses**, which accounts for the loss of work due to mechanical and electrical losses in the compressor in Watts. This field was previously known as Parameter 3.

Field: Compressor Efficiency

This numeric field defines the estimated parameter of the **compressor's efficiency**. The compressor efficiency is formulated as the equation below:

$$\eta = \frac{\dot{W}_{Theoretical}}{\dot{W}_{CompInput} - \dot{W}_{Loss}}$$

This field was previously know as Parameter 4.

Field: Compressor Piston Displacement

This numeric field defines the estimated parameter **piston displacement of the compressor** in m³/s. This field was part of what was previously known as Parameter 5. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

Field: Compressor Suction/Discharge Pressure Drop

This numeric field defines the estimated parameter **pressure drop at the compressor suction** and discharge in Pascals (N/m²). This field was part of what was previously known as Parameter 6. It should be used when the Compressor type is either Reciprocating and Rotary. The field should be left blank when Compressor type is Scroll.

Field: Compressor Clearance Factor

This numeric field defines the estimated parameter **clearance factor of the compressor**. This parameter is dimensionless. This field was part of what was previously known as Parameter 7. It should only be used when the Compressor type is Reciprocating. The field should be left blank when Compressor type is Scroll or Rotary.

Field: Refrigerant Volume Flow Rate

This numeric field defines the **refrigerant volume flow rate** at the beginning of the compression [m³/s]. This field was part of what was previously known as Parameter 6. It

should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

Field: Volume Ratio

This numeric field defines the **built-in-volume ratio**. This field was part of what was previously known as Parameter 6. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

Field: Leak Rate Coefficient

This numeric field defines the coefficient for the relationship between **pressure ratio and leakage rate**. This field was part of what was previously known as Parameter 7. It should only be used when the Compressor type is Scroll. The field should be left blank when Compressor type is Reciprocating or Rotary.

Field: Source Side Heat Transfer Coefficient

This numeric field defines the estimated parameter **source side heat transfer coefficient** in W/K. This field was part of what was previously known as Parameter 8. It should only be used when the Source Side Fluid Name is Water.

Field: Source Side Heat Transfer Resistance1

This numeric field defines the estimated parameter **source side heat transfer resistance 1**. Unit is dimensionless. This field was part of what was previously known as Parameter 8. It should only be used when the Source Side Fluid Name is an antifreeze.

Field: Source Side Heat Transfer Resistance2

This numeric field defines the estimated parameter **source side heat transfer resistance 2**. Unit is W/K. This field was previously known as Parameter 9. It should only be used when the Source Side Fluid Name is an antifreeze.

Coil:Heating:WaterToAirHeatPump:EquationFit

The Water to Air Heating Equation Fit Coil is a simple curve-fit model that requires coefficients generated from the heat pump catalog data. This is an equation-fit model that resembles a black box with no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data.

Field: Name

This alpha field contains the identifying name for the coil. Any reference to this coil by another object (e.g., AirLoopHVAC:UnitaryHeatPump:WaterToAir) will use this name.

Field: Water Inlet Node Name

This alpha field contains the heating coil source side inlet node name.

Field: Water Outlet Node Name

This alpha field contains the heating coil source side outlet node name.

Field: Air Inlet Node Name

This alpha field contains the heating coil air inlet node name.

Field: Air Outlet Node Name

This alpha field contains the heating coil air outlet node name.

Field: Rated Air Flow Rate

This numeric field contains the rated volumetric air flow rate on the load side of the heat pump in m³/s. This field is autosizable.

Field: Rated Water Flow Rate

This numeric field contains the rated volumetric water flow rate on the source side of the heat pump in m³/s. This field is autosizable.

Field: Rated Heating Capacity

This numeric field contains the rated heating capacity of the heat pump in W. This field is autosizable.

Field: Rated Heating Coefficient of Performance

This numeric field contains the rated heating coefficient of performance of the heat pump.

Field: Heating Capacity Coefficient 1-5

These numeric fields contain the first to fifth coefficient for the heat pump capacity.

Field: Heating Power Consumption Coefficient 1-5

These numeric fields contain the first to fifth coefficient for the heat pump power consumption.

Water to Air Heat Pump Heating Coil (parameter Estimation and Equation Fit)
Outputs

Coil:Heating:WaterToAirHeatPump:ParameterEstimation and
Coil:Heating:WaterToAirHeatPump:EquationFit have the same output variables listed as follows;

HVAC, Average, WatertoAirHP Power [W]
HVAC, Average, WatertoAirHP Load Side Total Heat Transfer Rate [W]
HVAC, Average, WatertoAirHP Load Side Sensible Heat Transfer Rate [W]
HVAC, Average, WatertoAirHP Source Side Heat Transfer Rate [W]
HVAC, Average, WatertoAirHP Part Load Ratio
HVAC, Average, WatertoAirHP Duty Factor
HVAC, Average, WatertoAirHP Load Side Mass Flow Rate[kg/s]
HVAC, Average, WatertoAirHP Load Side Inlet Dry Bulb Temperature [C]
HVAC, Average, WatertoAirHP Load Side Inlet Humidity Ratio [kg/kg]
HVAC, Average, WatertoAirHP Load Side Outlet Dry Bulb Temperature [C]

HVAC, Average, WatertoAirHP Load Side Outlet Humidity Ratio [kg/kg]
HVAC, Average, WatertoAirHP Source Side Mass Flow Rate[kg/s]
HVAC, Average, WatertoAirHP Source Side Inlet Temperature [C]
HVAC, Average, WatertoAirHP Source Side Outlet Temperature [C]
HVAC, Sum, WatertoAirHP Heating Electric Consumption [J]
HVAC, Sum, WatertoAirHP Load Side Total Heating Energy [J]
HVAC, Sum, WatertoAirHP Source Side Heating Energy [J]

WatertoAirHP Power [W]

This output variable is the average electric consumption rate of the heat pump in Watts over the timestep being reported.

WatertoAirHP Load Side Total Heat Transfer Rate [W]

The output variable is the average total heating capacity provide by the heat pump which includes the sensible and latent capacity in Watts over the timestep being reported.

WatertoAirHP Load Side Sensible Heat Transfer Rate [W]

The output variable is the average sensible heating capacity provide by the heat pump in Watts over the timestep being reported. For heating mode, the sensible capacity is equal to the total capacity.

WatertoAirHP Source Side Total Heat Transfer Rate [W]

The output variable is the average heat absorbed at the heat pump evaporator in Watts over the timestep being reported.

WatertoAirHP Part-Load Ratio

This output variable is the ratio of the part-load capacity to the steady state capacity of the WatertoAirHP coil. For the cycling fan mode, the runtime fraction for the heat pump compressor may be different from the compressor part-load ratio reported here due to the part-load performance of the WatertoAirHP coil (delay at start-up to reach steady-state output). In general, runtime fractions are reported by individual components where appropriate.

WatertoAirHP Duty Factor

This output variable is the function of the part load ratio (PLR, part-load capacity/ steady state capacity). The duty factor or part load fraction accounts for efficiency losses due to compressor cycling.

WatertoAirHP Load Side Mass Flow Rate [kg/s]

The output variable is the average air mass flow rate going through the heat pump over the timestep being reported.

WatertoAirHP Load Side Inlet Dry Bulb Temperature [C]

The output variable is the average entering air dry-bulb temperature over the timestep being reported.

WatertoAirHP Load Side Inlet Humidity Ratio [kg/kg]

The output variable is the average entering air dry humidity ratio over the timestep being reported.

WatertoAirHP Load Side Outlet Dry Bulb Temperature [C]
